## Notes for CMOS Devices

### 1. Precaution against ESD for semiconductors

Strong electric field, when exposed to a MOS device, can cause destruction of the gate oxide and ultimately degrade the device operation. Steps must be taken to stop generation of static electricity as much as possible, and quickly dissipate it once, when it has occurred. Environmental control must be adequate. When it is dry, humidifier should be used. It is recommended to avoid using insulators that easily build static electricity. Semiconductor devices must be stored and transported in an anti-static container, static shielding bag or conductive material. All test and measurement tools including work bench and floor should be grounded. The operator should be grounded using wrist strap. Semiconductor devices must not be touched with bare hands. Similar precautions need to be taken for PW boards with semiconductor devices on it.

### 2. Handling of unused input pins for CMOS

No connection for CMOS device inputs can be cause of malfunction. If no connection is provided to the input pins, it is possible that an internal input level may be generated due to noise, etc., hence causing malfunction. CMOS devices behave differently than Bipolar or NMOS devices. Input levels of CMOS devices must be fixed high or low by using a pull-up or pull-down circuitry. Each unused pin should be connected to VDD or GND with a resistor, if it is considered to have a possibility of being an output pin. All handling related to the unused pins must be judged device by device and related specifications governing the devices.

### 3. Status before initialization of MOS devices

Power-on does not necessarily define initial status of MOS device. Production process of MOS does not define the initial operation status of the device. Immediately after the power source is turned ON, the devices with reset function have not yet been initialized. Hence, power-on does not guarantee out-pin levels, I/O settings or contents of registers. Device is not initialized until the reset signal is received. Reset operation must be executed immediately after power-on for devices having reset function.

- Notes:**
- At the start condition, the first clock pulse is generated after the hold time
  - The system requires a minimum of 300ns hold time Internally for the SDA signal ( at VIH-min. of SCL00 signal )  
In order to occupy the undefined area at the falling edge of SCL00.
  - If the system does not extend the SCL00 signal low hold time ( tLOW ), only the maximum data hold time ( tHD:DAT ) needs to be satisfied.
  - The high-speed-mode IIC bus can be used In a normal-mode IIC bus system.  
In this case, set the high-speed-mode IIC bus so that It meets the following conditions.  
- If the system does not extend the SCL00 signal's low state hold time:  
SU:DAT?250ns  
- If the system extends the SCL00 signal's low state hold time:  
Transmit the following data bit to the SDA00 line prior to releasing the SCL00 line  
(tRmax.+tSU:DAT=1000+250=1250ns: Normal mode IIC bus specification ).

## 3.2 Product Marking

### 3.2.1 Marking of pin 1 at a QFP (Quad Flat Package)

Example 1: The index mark for pin 1 is the beveled edge of the package

Example 2: The index mark for pin 1 is a round notch at one of the 4 edges. In this case, the shape of all edges is identical (usually beveled).

Example 3: For production reasons, two or more similar notches may be located at the top of the package. In such a case the index marker for pin 1 is a round notch with an additional mark in it.

**Note:** RoHS compliant devices have an additional dot at the top side. Do not mix it up with the marking for pin 1. For details see 3.2.2 "Identification of Lead-Free Products" on page 35.

### 3.2.2 Identification of Lead-Free Products

Lead-Free products are marked with a dot "•". The marking methods are the paint or the laser (It doesn't sink in). The shape of lead-free marks is a circle.
