

Automotive DDR2 SDRAM

MT47H64M8 – 16 Meg x 8 x 4 banks
MT47H32M16 – 8 Meg x 16 x 4 banks

Features

- $V_{DD} = 1.8V \pm 0.1V$, $V_{DDQ} = 1.8V \pm 0.1V$
- JEDEC-standard 1.8V I/O (SSTL_18-compatible)
- Differential data strobe (DQS, DQS#) option
- 4n-bit prefetch architecture
- Duplicate output strobe (RDQS) option for x8
- DLL to align DQ and DQS transitions with CK
- 4 internal banks for concurrent operation
- Programmable CAS latency (CL)
- Posted CAS additive latency (AL)
- WRITE latency = READ latency - 1 t_{CK}
- Selectable burst lengths: 4 or 8
- Adjustable data-output drive strength
- 64ms, 8192-cycle refresh
- On-die termination (ODT)
- RoHS-compliant
- Supports JEDEC clock jitter specification
- AEC-Q100
- PPAP submission
- 8D response time

Options¹

- Configuration
 - 64 Meg x 8 (16 Meg x 8 x 4 banks) 64M8
 - 32 Meg x 16 (8 Meg x 16 x 4 banks) 32M16
- FBGA package (Pb-free) – x16
 - 84-ball FBGA (8mm x 12.5mm) Rev. H NF
- FBGA package (Pb-free) – x8
 - 60-ball FBGA (8mm x 10mm) Rev. H SH
- Timing – cycle time
 - 2.5ns @ CL = 5 (DDR2-800) -25E
 - 2.5ns @ CL = 6 (DDR2-800) -25
 - 3.0ns @ CL = 4 (DDR2-667) -3E
 - 3.0ns @ CL = 5 (DDR2-667) -3
- Special options
 - Standard None
 - Automotive grade A
- Operating temperature
 - Industrial ($-40^{\circ}\text{C} \leq T_C \leq +95^{\circ}\text{C}$; $-40^{\circ}\text{C} \leq T_A \leq +85^{\circ}\text{C}$) IT
 - Automotive ($-40^{\circ}\text{C} \leq T_C \leq +105^{\circ}\text{C}$) AT
- Revision :H

Note: 1. Not all options listed can be combined to define an offered product. Use the Part Catalog Search on www.micron.com for product offerings and availability.

Table 1: Key Timing Parameters

Speed Grade	Data Rate (MT/s)					t_{RC} (ns)
	CL = 3	CL = 4	CL = 5	CL = 6	CL = 7	
-25E	400	533	800	800	n/a	55
-25	400	533	667	800	n/a	55
-3E	400	667	667	n/a	n/a	54
-3	400	533	667	n/a	n/a	55

Note: 1. Not all speeds and configurations are available in all packages.

FBGA Part Number System

Due to space limitations, FBGA-packaged components have an abbreviated part marking that is different from the part number. For a quick conversion of an FBGA code, see the FBGA Part Marking Decoder on Micron's Web site: <http://www.micron.com>.

Important Notes and Warnings

Micron Technology, Inc. ("Micron") reserves the right to make changes to information published in this document, including without limitation specifications and product descriptions. This document supersedes and replaces all information supplied prior to the publication hereof. You may not rely on any information set forth in this document if you obtain the product described herein from any unauthorized distributor or other source not authorized by Micron.

Automotive Applications. Products are not designed or intended for use in automotive applications unless specifically designated by Micron as automotive-grade by their respective data sheets. Distributor and customer/distributor shall assume the sole risk and liability for and shall indemnify and hold Micron harmless against all claims, costs, damages, and expenses and reasonable attorneys' fees arising out of, directly or indirectly, any claim of product liability, personal injury, death, or property damage resulting directly or indirectly from any use of non-automotive-grade products in automotive applications. Customer/distributor shall ensure that the terms and conditions of sale between customer/distributor and any customer of distributor/customer (1) state that Micron products are not designed or intended for use in automotive applications unless specifically designated by Micron as automotive-grade by their respective data sheets and (2) require such customer of distributor/customer to indemnify and hold Micron harmless against all claims, costs, damages, and expenses and reasonable attorneys' fees arising out of, directly or indirectly, any claim of product liability, personal injury, death, or property damage resulting from any use of non-automotive-grade products in automotive applications.

Critical Applications. Products are not authorized for use in applications in which failure of the Micron component could result, directly or indirectly in death, personal injury, or severe property or environmental damage ("Critical Applications"). Customer must protect against death, personal injury, and severe property and environmental damage by incorporating safety design measures into customer's applications to ensure that failure of the Micron component will not result in such harms. Should customer or distributor purchase, use, or sell any Micron component for any critical application, customer and distributor shall indemnify and hold harmless Micron and its subsidiaries, subcontractors, and affiliates and the directors, officers, and employees of each against all claims, costs, damages, and expenses and reasonable attorneys' fees arising out of, directly or indirectly, any claim of product liability, personal injury, or death arising in any way out of such critical application, whether or not Micron or its subsidiaries, subcontractors, or affiliates were negligent in the design, manufacture, or warning of the Micron product.

Customer Responsibility. Customers are responsible for the design, manufacture, and operation of their systems, applications, and products using Micron products. ALL SEMICONDUCTOR PRODUCTS HAVE INHERENT FAILURE RATES AND LIMITED USEFUL LIVES. IT IS THE CUSTOMER'S SOLE RESPONSIBILITY TO DETERMINE WHETHER THE MICRON PRODUCT IS SUITABLE AND FIT FOR THE CUSTOMER'S SYSTEM, APPLICATION, OR PRODUCT. Customers must ensure that adequate design, manufacturing, and operating safeguards are included in customer's applications and products to eliminate the risk that personal injury, death, or severe property or environmental damages will result from failure of any semiconductor component.

Limited Warranty. In no event shall Micron be liable for any indirect, incidental, punitive, special or consequential damages (including without limitation lost profits, lost savings, business interruption, costs related to the removal or replacement of any products or rework charges) whether or not such damages are based on tort, warranty, breach of contract or other legal theory, unless explicitly stated in a written agreement executed by Micron's duly authorized representative.

State Diagram

Figure 2: Simplified State Diagram

Note: 1. This diagram provides the basic command flow. It is not comprehensive and does not identify all timing requirements or possible command restrictions such as multibank interaction, power down, entry/exit, etc.

Functional Description

The DDR2 SDRAM uses a double data rate architecture to achieve high-speed operation. The double data rate architecture is essentially a $4n$ -prefetch architecture, with an interface designed to transfer two data words per clock cycle at the I/O balls. A single

READ or WRITE operation for the DDR2 SDRAM effectively consists of a single $4n$ -bit-wide, two-clock-cycle data transfer at the internal DRAM core and four corresponding n -bit-wide, one-half-clock-cycle data transfers at the I/O balls.

A bidirectional data strobe (DQS, DQS#) is transmitted externally, along with data, for use in data capture at the receiver. DQS is a strobe transmitted by the DDR2 SDRAM during READs and by the memory controller during WRITEs. DQS is edge-aligned with data for READs and center-aligned with data for WRITEs. The x16 offering has two data strobes, one for the lower byte (LDQS, LDQS#) and one for the upper byte (UDQS, UDQS#).

The DDR2 SDRAM operates from a differential clock (CK and CK#); the crossing of CK going HIGH and CK# going LOW will be referred to as the positive edge of CK. Commands (address and control signals) are registered at every positive edge of CK. Input data is registered on both edges of DQS, and output data is referenced to both edges of DQS as well as to both edges of CK.

Read and write accesses to the DDR2 SDRAM are burst-oriented; accesses start at a selected location and continue for a programmed number of locations in a programmed sequence. Accesses begin with the registration of an ACTIVATE command, which is then followed by a READ or WRITE command. The address bits registered coincident with the ACTIVATE command are used to select the bank and row to be accessed. The address bits registered coincident with the READ or WRITE command are used to select the bank and the starting column location for the burst access.

The DDR2 SDRAM provides for programmable read or write burst lengths of four or eight locations. DDR2 SDRAM supports interrupting a burst read of eight with another read or a burst write of eight with another write. An auto precharge function may be enabled to provide a self-timed row precharge that is initiated at the end of the burst access.

As with standard DDR SDRAM, the pipelined, multibank architecture of DDR2 SDRAM enables concurrent operation, thereby providing high, effective bandwidth by hiding row precharge and activation time.

A self refresh mode is provided, along with a power-saving, power-down mode.

All inputs are compatible with the JEDEC standard for SSTL_18. All full drive-strength outputs are SSTL_18-compatible.

Industrial Temperature

The industrial temperature (IT) option, if offered, has two simultaneous requirements: ambient temperature surrounding the device cannot be less than -40°C or greater than 85°C , and the case temperature cannot be less than -40°C or greater than 95°C . JEDEC specifications require the refresh rate to double when T_C exceeds 85°C ; this also requires use of the high-temperature self refresh option. Additionally, ODT resistance, input/output impedance, and I_{DD} values must be derated when T_C is $< 0^{\circ}\text{C}$ or $> 85^{\circ}\text{C}$.

Automotive Temperature

The automotive temperature (AAT) option, if offered, has two simultaneous requirements: ambient temperature surrounding the device cannot be less than -40°C or greater than 105°C , and the case temperature cannot be less than -40°C or greater than 105°C . JEDEC specifications require the refresh rate to double when T_C exceeds 85°C ; this also requires use of the high-temperature self refresh option. Additionally, ODT re-

sistance, input/output impedance, and I_{DD} values must be derated when T_C is $< 0^\circ\text{C}$ or $> 85^\circ\text{C}$.

General Notes

- The functionality and the timing specifications discussed in this data sheet are for the DLL-enabled mode of operation.
 - Throughout the data sheet, the various figures and text refer to DQs as “DQ.” The DQ term is to be interpreted as any and all DQ collectively, unless specifically stated otherwise. Additionally, the x16 is divided into 2 bytes: the lower byte and the upper byte. For the lower byte (DQ[7:0]), DM refers to LDM and DQS refers to LDQS. For the upper byte (DQ[15:8]), DM refers to UDM and DQS refers to UDQS.
 - A x16 device's DQ bus is comprised of two bytes. If only one of the bytes needs to be used, use the lower byte for data transfers and terminate the upper byte as noted:
 - Connect UDQS to ground via $1\text{k}\Omega^*$ resistor
 - Connect UDQS# to V_{DD} via $1\text{k}\Omega^*$ resistor
 - Connect UDM to V_{DD} via $1\text{k}\Omega^*$ resistor
 - Connect DQ[15:8] individually to either V_{SS} or V_{DD} via $1\text{k}\Omega^*$ resistors, or float DQ[15:8].
- *If ODT is used, $1\text{k}\Omega$ resistor should be changed to 4x that of the selected ODT.
- Complete functionality is described throughout the document, and any page or diagram may have been simplified to convey a topic and may not be inclusive of all requirements.
 - Any specific requirement takes precedence over a general statement.

Functional Block Diagrams

The DDR2 SDRAM is a high-speed CMOS, dynamic random access memory. It is internally configured as a multibank DRAM.

Figure 6: 84-Ball FBGA – x16 Ball Assignments (Top View)

Table 3: FBGA 84-Ball – x16 and 60-Ball – x8 Descriptions

Symbol	Type	Description
A[12:0] (x16) A[13:0] (x8)	Input	Address inputs: Provide the row address for ACTIVATE commands, and the column address and auto precharge bit (A10) for READ/WRITE commands, to select one location out of the memory array in the respective bank. A10 sampled during a PRECHARGE command determines whether the PRECHARGE applies to one bank (A10 LOW, bank selected by BA[1:0]) or all banks (A10 HIGH). The address inputs also provide the op-code during a LOAD MODE command.
BA0, BA1	Input	Bank address inputs: BA[1:0] define to which bank an ACTIVATE, READ, WRITE, or PRECHARGE command is being applied. BA[1:0] define which mode register including MR, EMR, EMR(2), and EMR(3) is loaded during the LOAD MODE command.
CK, CK#	Input	Clock: CK and CK# are differential clock inputs. All address and control input signals are sampled on the crossing of the positive edge of CK and negative edge of CK#. Output data (DQ and DQS/DQS#) is referenced to the crossings of CK and CK#.
CKE	Input	Clock enable: CKE (registered HIGH) activates and CKE (registered LOW) deactivates clocking circuitry on the DDR2 SDRAM. The specific circuitry that is enabled/disabled is dependent on the DDR2 SDRAM configuration and operating mode. CKE LOW provides precharge power-down and SELF REFRESH operations (all banks idle), or ACTIVATE power-down (row active in any bank). CKE is synchronous for power-down entry, power-down exit, output disable, and for SELF REFRESH entry. CKE is asynchronous for SELF REFRESH exit. Input buffers (excluding CK, CK#, CKE, and ODT) are disabled during POWER-DOWN. Input buffers (excluding CKE) are disabled during SELF REFRESH. CKE is an SSTL_18 input but will detect a LVCMOS LOW level once V _{DD} is applied during first power-up. After V _{REF} has become stable during the power-on and initialization sequence, it must be maintained for proper operation of the CKE receiver. For proper SELF-REFRESH operation, V _{REF} must be maintained.
CS#	Input	Chip select: CS# enables (registered LOW) and disables (registered HIGH) the command decoder. All commands are masked when CS# is registered high. CS# provides for external bank selection on systems with multiple ranks. CS# is considered part of the command code.
LDM, UDM, DM	Input	Input data mask: DM is an input mask signal for write data. Input data is masked when DM is sampled HIGH along with that input data during a WRITE access. DM is sampled on both edges of DQS. Although DM balls are input-only, the DM loading is designed to match that of DQ and DQS balls. LDM is DM for lower byte DQ[7:0] and UDM is DM for upper byte DQ[15:8].
ODT	Input	On-die termination: ODT (registered HIGH) enables termination resistance internal to the DDR2 SDRAM. When enabled, ODT is only applied to each of the following balls: DQ[15:0], LDM, UDM, LDQS, LDQS#, UDQS, and UDQS# for the x16; DQ[7:0], DQS, DQS#, RDQS, RDQS#, and DM for the x8. The ODT input will be ignored if disabled via the LOAD MODE command.
RAS#, CAS#, WE#	Input	Command inputs: RAS#, CAS#, and WE# (along with CS#) define the command being entered.
DQ[15:0] (x16) DQ[7:0] (x8)	I/O	Data input/output: Bidirectional data bus for 32 Meg x 16. Bidirectional data bus for 64 Meg x 8.
DQS, DQS#	I/O	Data strobe: Output with read data, input with write data for source synchronous operation. Edge-aligned with read data, center-aligned with write data. DQS# is only used when differential data strobe mode is enabled via the LOAD MODE command.

Table 3: FBGA 84-Ball – x16 and 60-Ball – x8 Descriptions (Continued)

Symbol	Type	Description
LDQS, LDQS#	I/O	Data strobe for lower byte: Output with read data, input with write data for source synchronous operation. Edge-aligned with read data, center-aligned with write data. LDQS# is only used when differential data strobe mode is enabled via the LOAD MODE command.
UDQS, UDQS#	I/O	Data strobe for upper byte: Output with read data, input with write data for source synchronous operation. Edge-aligned with read data, center-aligned with write data. UDQS# is only used when differential data strobe mode is enabled via the LOAD MODE command.
RDQS, RDQS#	Output	Redundant data strobe: For 64 Meg x 8 only. RDQS is enabled/disabled via the load mode command to the extended mode register (EMR). When RDQS is enabled, RDQS is output with read data only and is ignored during write data. When RDQS is disabled, ball B3 becomes data mask (see DM ball). RDQS# is only used when RDQS is enabled <i>and</i> differential data strobe mode is enabled.
V _{DD}	Supply	Power supply: 1.8V ±0.1V.
V _{DDQ}	Supply	DQ power supply: 1.8V ±0.1V. Isolated on the device for improved noise immunity.
V _{DDL}	Supply	DLL power supply: 1.8V ±0.1V.
V _{REF}	Supply	SSTL_18 reference voltage (V _{DDQ} /2).
V _{SS}	Supply	Ground.
V _{SSDL}	Supply	DLL ground: Isolated on the device from V _{SS} and V _{SSQ} .
V _{SSQ}	Supply	DQ ground: Isolated on the device for improved noise immunity.
NC	–	No connect: These balls should be left unconnected.
NU	–	Not used: If EMR(E10) = 0: x16, A8 = UDQS# and E8 = LDQS#; x8, A2 = RDQS# and A8 = DQS#. If EMR(E10) = 1: x16, A8 = NU and E8 = NU; x8, A2 = NU and A8 = NU.
RFU	–	Reserved for future use: Bank address BA2, row address bits A13 (x16 only), A14, and A15.

Packaging

Package Dimensions

Figure 7: 84-Ball FBGA (8mm x 12.5mm) – x16; "NF" Die Rev :H

- Notes:
1. All dimensions are in millimeters.
 2. Solder ball material: SAC305 (96.5% Sn, 3% Ag, 0.5% Cu).

Figure 8: 60-Ball FBGA (8mm x 10mm) – x8; "SH" Die Rev :H

- Notes:
1. All dimensions are in millimeters.
 2. Solder ball material: SAC305 (96.5% Sn, 3% Ag, 0.5% Cu).

FBGA Package Capacitance

Table 4: Input Capacitance

Parameter	Symbol	Min	Max	Units	Notes
Input capacitance: CK, CK#	C_{CK}	1.0	2.0	pF	1
Delta input capacitance: CK, CK#	C_{DCK}	–	0.25	pF	2, 3
Input capacitance: Address balls, bank address balls, CS#, RAS#, CAS#, WE#, CKE, ODT	C_I	1.0	2.0	pF	1, 4
Delta input capacitance: Address balls, bank address balls, CS#, RAS#, CAS#, WE#, CKE, ODT	C_{DI}	–	0.25	pF	2, 3
Input/output capacitance: DQ, DQS, DM, NF	C_{IO}	2.5	4.0	pF	1, 5
Delta input/output capacitance: DQ, DQS, DM, NF	C_{DIO}	–	0.5	pF	2, 3

- Notes:
1. This parameter is sampled. $V_{DD} = 1.8V \pm 0.1V$, $V_{DDQ} = 1.8V \pm 0.1V$, $V_{REF} = V_{SS}$, $f = 100$ MHz, $T_C = 25^\circ C$, $V_{OUT(DC)} = V_{DDQ}/2$, V_{OUT} (peak-to-peak) = 0.1V. DM input is grouped with I/O balls, reflecting the fact that they are matched in loading.
 2. The capacitance per ball group will not differ by more than this maximum amount for any given device.
 3. ΔC are not pass/fail parameters; they are targets.
 4. Reduce MAX limit by 0.25pF for -25 and -25E speed devices.
 5. Reduce MAX limit by 0.5pF for -3, -3E, -5E, -25, -25E, and -37E speed devices.

Electrical Specifications – Absolute Ratings

Stresses greater than those listed may cause permanent damage to the device. This is a stress rating only, and functional operation of the device at these or any other conditions outside those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect reliability.

Table 5: Absolute Maximum DC Ratings

Parameter	Symbol	Min	Max	Units	Notes
V_{DD} supply voltage relative to V_{SS}	V_{DD}	-1.0	2.3	V	1
V_{DDQ} supply voltage relative to V_{SSQ}	V_{DDQ}	-0.5	2.3	V	1, 2
V_{DDL} supply voltage relative to V_{SSL}	V_{DDL}	-0.5	2.3	V	1
Voltage on any ball relative to V_{SS}	V_{IN}, V_{OUT}	-0.5	2.3	V	3
Input leakage current; any input $0V \leq V_{IN} \leq V_{DD}$; all other balls not under test = 0V	I_I	-5	5	μA	
Output leakage current; $0V \leq V_{OUT} \leq V_{DDQ}$; DQ and ODT disabled	I_{OZ}	-5	5	μA	
V_{REF} leakage current; V_{REF} = valid V_{REF} level	I_{VREF}	-2	2	μA	

- Notes:
1. V_{DD} , V_{DDQ} , and V_{DDL} must be within 300mV of each other at all times; this is not required when power is ramping down.
 2. $V_{REF} \leq 0.6 \times V_{DDQ}$; however, V_{REF} may be $\geq V_{DDQ}$ provided that $V_{REF} \leq 300mV$.
 3. Voltage on any I/O may not exceed voltage on V_{DDQ} .

Temperature and Thermal Impedance

It is imperative that the DDR2 SDRAM device's temperature specifications, shown in Table 6 (page 23), be maintained in order to ensure the junction temperature is in the proper operating range to meet data sheet specifications. An important step in maintaining the proper junction temperature is using the device's thermal impedances correctly. The thermal impedances are listed in Table 7 (page 24) for the applicable and available die revision and packages.

Incorrectly using thermal impedances can produce significant errors. Read Micron technical note TN-00-08, "Thermal Applications," prior to using the thermal impedances listed in Table 7. For designs that are expected to last several years and require the flexibility to use several DRAM die shrinks, consider using final target theta values (rather than existing values) to account for increased thermal impedances from the die size reduction.

The DDR2 SDRAM device's safe junction temperature range can be maintained when the T_C specification is not exceeded. In applications where the device's ambient temperature is too high, use of forced air and/or heat sinks may be required in order to satisfy the case temperature specifications.

Table 6: Temperature Limits

Parameter	Symbol	Min	Max	Units	Notes
Storage temperature	T_{STG}	-55	150	°C	1
Operating temperature: commercial	T_C	0	85	°C	2, 3
Operating temperature: industrial	T_C	-40	95	°C	2, 3, 4
	T_A	-40	85	°C	4, 5
Operating temperature: automotive	T_C	-40	105	°C	2, 3, 4
	T_A	-40	105	°C	4, 5

- Notes:
1. MAX storage case temperature T_{STG} is measured in the center of the package, as shown in Figure 9. This case temperature limit is allowed to be exceeded briefly during package reflow, as noted in Micron technical note TN-00-15, "Recommended Soldering Parameters."
 2. MAX operating case temperature T_C is measured in the center of the package, as shown in Figure 9.
 3. Device functionality is not guaranteed if the device exceeds maximum T_C during operation.
 4. Both temperature specifications must be satisfied.
 5. Operating ambient temperature surrounding the package.

Figure 9: Example Temperature Test Point Location

512Mb: x8, x16 Automotive DDR2 SDRAM Electrical Specifications – Absolute Ratings

Table 7: Thermal Impedance

Die Revision	Package	Substrate	Θ_{JA} (°C/W) Airflow = 0m/s	Θ_{JA} (°C/W) Airflow = 1m/s	Θ_{JA} (°C/W) Airflow = 2m/s	Θ_{JB} (°C/W)	Θ_{JC} (°C/W)
H ¹	60-ball	Low Conductivity	85.4	70.6	64.5	42.8	11.7
		High Conductivity	63.2	56.1	52.8		
	84-ball	Low Conductivity	80.8	67.0	61.6	44.7	11.7
		High Conductivity	59.7	53.3	50.7		

Note: 1. Thermal resistance data is based on a number of samples from multiple lots and should be viewed as a typical number.

Electrical Specifications – I_{DD} Parameters

I_{DD} Specifications and Conditions

Table 8: General I_{DD} Parameters

I _{DD} Parameters	-25E	-25	-3E	-3	Units
CL (I _{DD})	5	6	4	5	t _{CK}
t _{RCD} (I _{DD})	12.5	15	12	15	ns
t _{RC} (I _{DD})	57.5	60	57	60	ns

I_{DD7} Conditions

The detailed timings are shown below for I_{DD7}. Where general I_{DD} parameters in the General Parameters Table conflict with pattern requirements in the I_{DD7} Timing Patterns Table, then the I_{DD7} timing patterns requirements take precedence.

Table 9: I_{DD7} Timing Patterns (4-Bank Interleave READ Operation)

Speed Grade	I _{DD7} Timing Patterns
Timing patterns for 4-bank x8/x16 devices	
-5E	A0 RA0 A1 RA1 A2 RA2 A3 RA3 D D D
-3	A0 RA0 D D A1 RA1 D D A2 RA2 D D A3 RA3 D D D D D D
-3E	A0 RA0 D D A1 RA1 D D A2 RA2 D D A3 RA3 D D D D D D
-25	A0 RA0 D D A1 RA1 D D A2 RA2 D D A3 RA3 D D D D D D D D D D
-25E	A0 RA0 D D A1 RA1 D D A2 RA2 D D A3 RA3 D D D D D D D D D D

- Notes:
1. A = active; RA = read auto precharge; D = deselect.
 2. All banks are being interleaved at t_{RC} (I_{DD}) without violating t_{RRD} (I_{DD}) using a BL = 4.
 3. Control and address bus inputs are stable during DESELECTs.

Table 10: DDR2 I_{DD} Specifications and Conditions (Die Revision H)

Notes: 1–7 apply to the entire table

Parameter/Condition	Symbol	Configuration	-25E	-3	Units
Operating one bank active-precharge current: $t_{CK} = t_{CK} (I_{DD})$, $t_{RC} = t_{RC} (I_{DD})$, $t_{RAS} = t_{RAS} \text{ MIN} (I_{DD})$; CKE is HIGH, CS# is HIGH between valid commands; address bus inputs are switching; Data bus inputs are switching	I _{DD0}	x8	65	60	mA
		x16	80	75	
Operating one bank active-read-precharge current: I _{OUT} = 0mA; BL = 4, CL = CL (I _{DD}), AL = 0; $t_{CK} = t_{CK} (I_{DD})$, $t_{RC} = t_{RC} (I_{DD})$, $t_{RAS} = t_{RAS} \text{ MIN} (I_{DD})$, $t_{RCD} = t_{RCD} (I_{DD})$; CKE is HIGH, CS# is HIGH between valid commands; address bus inputs are switching; Data pattern is same as I _{DD4W}	I _{DD1}	x8	75	70	mA
		x16	95	90	
Precharge power-down current: All banks idle; $t_{CK} = t_{CK} (I_{DD})$; CKE is LOW; Other control and address bus inputs are stable; Data bus inputs are floating	I _{DD2P}	x8, x16	10	10	mA
Precharge quiet standby current: All banks idle; $t_{CK} = t_{CK} (I_{DD})$; CKE is HIGH, CS# is HIGH; Other control and address bus inputs are stable; Data bus inputs are floating	I _{DD2Q}	x8	24	22	mA
		x16	26	24	
Precharge standby current: All banks idle; $t_{CK} = t_{CK} (I_{DD})$; CKE is HIGH, CS# is HIGH; Other control and address bus inputs are switching; Data bus inputs are switching	I _{DD2N}	x8	28	25	mA
		x16	30	27	
Active power-down current: All banks open; $t_{CK} = t_{CK} (I_{DD})$; CKE is LOW; Other control and address bus inputs are stable; Data bus inputs are floating	I _{DD3Pf}	Fast PDN exit MR12 = 0	20	18	mA
	I _{DD3Ps}	Slow PDN exit MR12 = 1	15	15	
Active standby current: All banks open; $t_{CK} = t_{CK} (I_{DD})$, $t_{RAS} = t_{RAS} \text{ MAX} (I_{DD})$, $t_{RP} = t_{RP} (I_{DD})$; CKE is HIGH, CS# is HIGH between valid commands; Other control and address bus inputs are switching; Data bus inputs are switching	I _{DD3N}	x8	33	30	mA
		x16	35	32	
Operating burst write current: All banks open, continuous burst writes; BL = 4, CL = CL (I _{DD}), AL = 0; $t_{CK} = t_{CK} (I_{DD})$, $t_{RAS} = t_{RAS} \text{ MAX} (I_{DD})$, $t_{RP} = t_{RP} (I_{DD})$; CKE is HIGH, CS# is HIGH between valid commands; address bus inputs are switching; Data bus inputs are switching	I _{DD4W}	x8	125	115	mA
		x16	160	135	
Operating burst read current: All banks open, continuous burst reads, I _{OUT} = 0mA; BL = 4, CL = CL (I _{DD}), AL = 0; $t_{CK} = t_{CK} (I_{DD})$, $t_{RAS} = t_{RAS} \text{ MAX} (I_{DD})$, $t_{RP} = t_{RP} (I_{DD})$; CKE is HIGH, CS# is HIGH between valid commands; address bus inputs are switching; Data bus inputs are switching	I _{DD4R}	x8	120	110	mA
		x16	150	125	

Table 10: DDR2 I_{DD} Specifications and Conditions (Die Revision H) (Continued)

Notes: 1–7 apply to the entire table

Parameter/Condition	Symbol	Configuration	-25E	-3	Units
Burst refresh current: $t_{CK} = t_{CK}(I_{DD})$; refresh command at every $t_{RFC}(I_{DD})$ interval; CKE is HIGH, CS# is HIGH between valid commands; Other control and address bus inputs are switching; Data bus inputs are switching	I _{DD5}	x8	95	90	mA
		x16	100	90	
Self refresh current: CK and CK# at 0V; CKE $\leq 0.2V$; Other control and address bus inputs are floating; Data bus inputs are floating	I _{DD6}	x8, x16	7	7	mA
Operating bank interleave read current: All bank interleaving reads, I _{OUT} = 0mA; BL = 4, CL = CL(I _{DD}), AL = $t_{RCD}(I_{DD}) - 1 \times t_{CK}(I_{DD})$; $t_{CK} = t_{CK}(I_{DD})$, $t_{RC} = t_{RC}(I_{DD})$, $t_{RRD} = t_{RRD}(I_{DD})$, $t_{RCD} = t_{RCD}(I_{DD})$; CKE is HIGH, CS# is HIGH between valid commands; address bus inputs are stable during deselects; Data bus inputs are switching; See I _{DD7} Conditions (page 25) for details	I _{DD7}	x8	150	140	mA
		x16	215	200	

- Notes:
- I_{DD} specifications are tested after the device is properly initialized. $0^{\circ}\text{C} \leq T_C \leq +85^{\circ}\text{C}$.
 - V_{DD} = +1.8V $\pm 0.1V$, V_{DDQ} = +1.8V $\pm 0.1V$, V_{DDL} = +1.8V $\pm 0.1V$, V_{REF} = V_{DDQ}/2.
 - I_{DD} parameters are specified with ODT disabled.
 - Data bus consists of DQ, DM, DQS, DQS#, RDQS, RDQS#, LDQS, LDQS#, UDQS, and UDQS#. I_{DD} values must be met with all combinations of EMR bits 10 and 11.
 - Definitions for I_{DD} conditions:
 - LOW** $V_{IN} \leq V_{IL(AC)max}$
 - HIGH** $V_{IN} \geq V_{IH(AC)min}$
 - Stable** Inputs stable at a HIGH or LOW level
 - Floating** Inputs at V_{REF} = V_{DDQ}/2
 - Switching** Inputs changing between HIGH and LOW every other clock cycle (once per two clocks) for address and control signals
 - Switching** Inputs changing between HIGH and LOW every other data transfer (once per clock) for DQ signals, not including masks or strobes
 - I_{DD1}, I_{DD4R}, and I_{DD7} require A12 in EMR1 to be enabled during testing.
 - The following I_{DD} values must be derated (I_{DD} limits increase) when operated outside of the range $0^{\circ}\text{C} \leq T_C \leq 85^{\circ}\text{C}$:
 - When $T_C \leq 0^{\circ}\text{C}$** I_{DD2P} and I_{DD3P(SLOW)} must be derated by 4%; I_{DD4R} and I_{DD4W} must be derated by 2%; and I_{DD6} and I_{DD7} must be derated by 7%
 - When $T_C \geq 85^{\circ}\text{C}$** I_{DD0}, I_{DD1}, I_{DD2N}, I_{DD2Q}, I_{DD3N}, I_{DD3P(FAST)}, I_{DD4R}, I_{DD4W}, and I_{DD5} must be derated by 2%; I_{DD2P} must be derated by 20%; I_{DD3P} slow must be derated by 30%; and I_{DD6} must be derated by 80% (I_{DD6} will increase by this amount if $T_C < 85^{\circ}\text{C}$ and the 2X refresh option is still enabled)

AC Timing Operating Specifications

Table 11: AC Operating Specifications and Conditions

- Notes:
1. All voltages are referenced to V_{SS} .
 2. Tests for AC timing, I_{DD} , and electrical AC and DC characteristics may be conducted at nominal reference/supply voltage levels, but the related specifications and the operation of the device are warranted for the full voltage range specified. ODT is disabled for all measurements that are not ODT-specific.
 3. Outputs measured with equivalent load (see Figure 13 (page 43)).
 4. AC timing and I_{DD} tests may use a V_{IL} -to- V_{IH} swing of up to 1.0V in the test environment, and parameter specifications are guaranteed for the specified AC input levels under normal use conditions. The slew rate for the input signals used to test the device is 1.0 V/ns for signals in the range between $V_{IL(AC)}$ and $V_{IH(AC)}$. Slew rates other than 1.0 V/ns may require the timing parameters to be derated as specified.
 5. The AC and DC input level specifications are as defined in the SSTL_18 standard (that is, the receiver will effectively switch as a result of the signal crossing the AC input level and will remain in that state as long as the signal does not ring back above [below] the DC input LOW [HIGH] level).
 6. CK and CK# input slew rate is referenced at 1 V/ns (2 V/ns if measured differentially).
 7. Operating frequency is only allowed to change during self refresh mode (see Figure 76 (page 118)), precharge power-down mode, or system reset condition (see Reset (page 119)). SSC allows for small deviations in operating frequency, provided the SSC guidelines are satisfied.
 8. The clock's $t_{CK} (AVG)$ is the average clock over any 200 consecutive clocks and $t_{CK} (AVG) MIN$ is the smallest clock rate allowed (except for a deviation due to allowed clock jitter). Input clock jitter is allowed provided it does not exceed values specified. Also, the jitter must be of a random Gaussian distribution in nature.
 9. Spread spectrum is not included in the jitter specification values. However, the input clock can accommodate spread spectrum at a sweep rate in the range 8–60 kHz with an additional one percent $t_{CK} (AVG)$; however, the spread spectrum may not use a clock rate below $t_{CK} (AVG) MIN$ or above $t_{CK} (AVG) MAX$.
 10. MIN (t_{CL} , t_{CH}) refers to the smaller of the actual clock LOW time and the actual clock HIGH time driven to the device. The clock's half period must also be of a Gaussian distribution; $t_{CH} (AVG)$ and $t_{CL} (AVG)$ must be met with or without clock jitter and with or without duty cycle jitter. $t_{CH} (AVG)$ and $t_{CL} (AVG)$ are the average of any 200 consecutive CK falling edges. t_{CH} limits may be exceeded if the duty cycle jitter is small enough that the absolute half period limits ($t_{CH} [ABS]$, $t_{CL} [ABS]$) are not violated.
 11. $t_{HP} (MIN)$ is the lesser of t_{CL} and t_{CH} actually applied to the device CK and CK# inputs; thus, $t_{HP} (MIN) \geq$ the lesser of $t_{CL} (ABS) MIN$ and $t_{CH} (ABS) MIN$.
 12. The period jitter (t_{JITper}) is the maximum deviation in the clock period from the average or nominal clock allowed in either the positive or negative direction. JEDEC specifies tighter jitter numbers during DLL locking time. During DLL lock time, the jitter values should be 20 percent less than those noted in the table (DLL locked).
 13. The half-period jitter (t_{JITdty}) applies to either the high pulse of clock or the low pulse of clock; however, the two cumulatively can not exceed t_{JITper} .
 14. The cycle-to-cycle jitter (t_{JITcc}) is the amount the clock period can deviate from one cycle to the next. JEDEC specifies tighter jitter numbers during DLL locking time. During DLL lock time, the jitter values should be 20 percent less than those noted in the table (DLL locked).
 15. The cumulative jitter error ($t_{ERR_{nper}}$), where n is 2, 3, 4, 5, 6–10, or 11–50 is the amount of clock time allowed to consecutively accumulate away from the average clock over any number of clock cycles.
 16. JEDEC specifies using $t_{ERR_{6-10per}}$ when derating clock-related output timing (see notes 19 and 48). Micron requires less derating by allowing $t_{ERR_{5per}}$ to be used.
 17. This parameter is not referenced to a specific voltage level but is specified when the device output is no longer driving (t_{RPST}) or beginning to drive (t_{RPRE}).

18. The inputs to the DRAM must be aligned to the associated clock, that is, the actual clock that latches it in. However, the input timing (in ns) references to the $t_{CK}^{(AVG)}$ when determining the required number of clocks. The following input parameters are determined by taking the specified percentage times the $t_{CK}^{(AVG)}$ rather than t_{CK} : t_{IPW} , t_{DIPW} , t_{DQSS} , t_{DQSH} , t_{DQSL} , t_{DSS} , t_{DSH} , t_{WPST} , and t_{WPRE} .
19. The DRAM output timing is aligned to the nominal or average clock. Most output parameters must be derated by the actual jitter error when input clock jitter is present; this will result in each parameter becoming larger. The following parameters are required to be derated by subtracting $t_{ERR_{Sper}}^{(MAX)}$: $t_{AC}^{(MIN)}$, $t_{DQCK}^{(MIN)}$, $t_{LZ_{DQS}}^{(MIN)}$, $t_{LZ_{DQ}}^{(MIN)}$, $t_{AON}^{(MIN)}$; while the following parameters are required to be derated by subtracting $t_{ERR_{Sper}}^{(MIN)}$: $t_{AC}^{(MAX)}$, $t_{DQCK}^{(MAX)}$, $t_{HZ}^{(MAX)}$, $t_{LZ_{DQS}}^{(MAX)}$, $t_{LZ_{DQ}}^{(MAX)}$, $t_{AON}^{(MAX)}$. The parameter $t_{RPRE}^{(MIN)}$ is derated by subtracting $t_{JITper}^{(MAX)}$, while $t_{RPRE}^{(MAX)}$, is derated by subtracting $t_{JITper}^{(MIN)}$. The parameter $t_{RPST}^{(MIN)}$ is derated by subtracting $t_{JITdty}^{(MAX)}$, while $t_{RPST}^{(MAX)}$, is derated by subtracting $t_{JITdty}^{(MIN)}$. Output timings that require $t_{ERR_{Sper}}$ derating can be observed to have offsets relative to the clock; however, the total window will not degrade.
20. When DQS is used single-ended, the minimum limit is reduced by 100ps.
21. t_{HZ} and t_{LZ} transitions occur in the same access time windows as valid data transitions. These parameters are not referenced to a specific voltage level, but specify when the device output is no longer driving (t_{HZ}) or begins driving (t_{LZ}).
22. $t_{LZ}^{(MIN)}$ will prevail over a $t_{DQCK}^{(MIN)} + t_{RPRE}^{(MAX)}$ condition.
23. This is not a device limit. The device will operate with a negative value, but system performance could be degraded due to bus turnaround.
24. It is recommended that DQS be valid (HIGH or LOW) on or before the WRITE command. The case shown (DQS going from High-Z to logic LOW) applies when no WRITES were previously in progress on the bus. If a previous WRITE was in progress, DQS could be HIGH during this time, depending on t_{DQSS} .
25. The intent of the "Don't Care" state after completion of the postamble is that the DQS-driven signal should either be HIGH, LOW, or High-Z, and that any signal transition within the input switching region must follow valid input requirements. That is, if DQS transitions HIGH (above $V_{IH[DC]min}$), then it must not transition LOW (below $V_{IH[DC]}$) prior to $t_{DQSH}^{(MIN)}$.
26. Referenced to each output group: x8 = DQS with DQ[7:0]; x16 = LDQS with DQ[7:0]; and UDQS with DQ[15:8].
27. The data valid window is derived by achieving other specifications: t_{HP} ($t_{CK}/2$), t_{DQSQ} , and t_{QH} ($t_{QH} = t_{HP} - t_{QHS}$). The data valid window derates in direct proportion to the clock duty cycle and a practical data valid window can be derived.
28. $t_{QH} = t_{HP} - t_{QHS}$; the worst case t_{QH} would be the lesser of $t_{CL}^{(ABS)} MAX$ or $t_{CH}^{(ABS)} MAX$ times $t_{CK}^{(ABS)} MIN - t_{QHS}$. Minimizing the amount of $t_{CH}^{(AVG)}$ offset and value of t_{JITdty} will provide a larger t_{QH} , which in turn will provide a larger valid data out window.
29. This maximum value is derived from the referenced test load. $t_{HZ}^{(MAX)}$ will prevail over $t_{DQCK}^{(MAX)} + t_{RPST}^{(MAX)}$ condition.
30. The values listed are for the differential DQS strobe (DQS and DQS#) with a differential slew rate of 2 V/ns (1 V/ns for each signal). There are two sets of values listed: t_{DSa} , t_{DH_a} and t_{DSb} , t_{DH_b} . The t_{DSa} , t_{DH_a} values (for reference only) are equivalent to the baseline values of t_{DSb} , t_{DH_b} at V_{REF} when the slew rate is 2 V/ns, differentially. The baseline values, t_{DSb} , t_{DH_b} , are the JEDEC-defined values, referenced from the logic trip points. t_{DSb} is referenced from $V_{IH(AC)}$ for a rising signal and $V_{IL(AC)}$ for a falling signal, while t_{DH_b} is referenced from $V_{IL(DC)}$ for a rising signal and $V_{IH(DC)}$ for a falling signal. If the differential DQS slew rate is not equal to 2 V/ns, then the baseline values must be derated by adding the values from Table 30 (page 56) and Table 31 (page 57). If the DQS differential strobe feature is not enabled, then the DQS strobe is single-ended and the baseline values must be derated using Table 32 (page 58). Single-ended DQS data timing is referenced at DQS crossing V_{REF} . The correct timing values

for a single-ended DQS strobe are listed in Table 33 (page 58)–Table 35 (page 59) on Table 33 (page 58), Table 34 (page 59), and Table 35 (page 59); listed values are already derated for slew rate variations and converted from baseline values to V_{REF} values.

31. V_{IL}/V_{IH} DDR2 overshoot/undershoot. See (page 0).
32. For each input signal—not the group collectively.
33. There are two sets of values listed for command/address: t_{IS_a} , t_{IH_a} and t_{IS_b} , t_{IH_b} . The t_{IS_a} , t_{IH_a} values (for reference only) are equivalent to the baseline values of t_{IS_b} , t_{IH_b} at V_{REF} when the slew rate is 1 V/ns. The baseline values, t_{IS_b} , t_{IH_b} , are the JEDEC-defined values, referenced from the logic trip points. t_{IS_b} is referenced from $V_{IH(AC)}$ for a rising signal and $V_{IL(AC)}$ for a falling signal, while t_{IH_b} is referenced from $V_{IL(DC)}$ for a rising signal and $V_{IH(DC)}$ for a falling signal. If the command/address slew rate is not equal to 1 V/ns, then the baseline values must be derated by adding the values from Table 28 (page 52) and Table 29 (page 53).
34. This is applicable to READ cycles only. WRITE cycles generally require additional time due to t_{WR} during auto pre-charge.
35. READs and WRITEs with auto precharge are allowed to be issued before t_{RAS} (MIN) is satisfied because t_{RAS} lock-out feature is supported in DDR2 SDRAM.
36. When a single-bank PRECHARGE command is issued, t_{RP} timing applies. t_{RPA} timing applies when the PRE-CHARGE (ALL) command is issued, regardless of the number of banks open. For 8-bank devices ($\geq 1\text{Gb}$), t_{RPA} (MIN) = t_{RP} (MIN) + t_{CK} (AVG) (Table 11 (page 28) lists t_{RP} [MIN] + t_{CK} [AVG] MIN).
37. This parameter has a two clock minimum requirement at any t_{CK} .
38. The t_{FAW} (MIN) parameter applies to all 8-bank DDR2 devices. No more than four bank-ACTIVATE commands may be issued in a given t_{FAW} (MIN) period. t_{RRD} (MIN) restriction still applies.
39. The minimum internal READ-to-PRECHARGE time. This is the time from which the last 4-bit prefetch begins to when the PRECHARGE command can be issued. A 4-bit prefetch is when the READ command internally latches the READ so that data will output CL later. This parameter is only applicable when $t_{RTP}/(2 \times t_{CK}) > 1$, such as frequencies faster than 533 MHz when $t_{RTP} = 7.5\text{ns}$. If $t_{RTP}/(2 \times t_{CK}) \leq 1$, then equation AL + BL/2 applies. t_{RAS} (MIN) has to be satisfied as well. The DDR2 SDRAM will automatically delay the internal PRECHARGE command until t_{RAS} (MIN) has been satisfied.
40. $t_{DAL} = (nWR) + (t_{RP}/t_{CK})$. Each of these terms, if not already an integer, should be rounded up to the next integer. t_{CK} refers to the application clock period; nWR refers to the t_{WR} parameter stored in the MR9–MR11. For example, -37E at $t_{CK} = 3.75\text{ns}$ with t_{WR} programmed to four clocks would have $t_{DAL} = 4 + (15\text{ns}/3.75\text{ns}) \text{ clocks} = 4 + (4) \text{ clocks} = 8 \text{ clocks}$.
41. The refresh period is 64ms (commercial) or 32ms (industrial and automotive). This equates to an average refresh rate of 7.8125 μs (commercial) or 3.9607 μs (industrial and automotive). To ensure all rows of all banks are properly refreshed, 8192 REFRESH commands must be issued every 64ms (commercial) or 32ms (industrial and automotive). The JEDEC t_{RFC} MAX of 70,000ns is not required as bursting of AUTO REFRESH commands is allowed.
42. t_{DELAY} is calculated from $t_{IS} + t_{CK} + t_{IH}$ so that CKE registration LOW is guaranteed prior to CK, CK# being removed in a system RESET condition (see (page 0)).
43. t_{ISXR} is equal to t_{IS} and is used for CKE setup time during self refresh exit, as shown in Figure 66 (page 110).
44. t_{CKE} (MIN) of three clocks means CKE must be registered on three consecutive positive clock edges. CKE must remain at the valid input level the entire time it takes to achieve the three clocks of registration. Thus, after any CKE transition, CKE may not transition from its valid level during the time period of $t_{IS} + 2 \times t_{CK} + t_{IH}$.
45. The half-clock of t_{AOFD} 's 2.5 t_{CK} assumes a 50/50 clock duty cycle. This half-clock value must be derated by the amount of half-clock duty cycle error. For example, if the clock duty cycle was 47/53, t_{AOFD} would actually be 2.5 - 0.03, or 2.47, for t_{AOF} (MIN) and 2.5 + 0.03, or 2.53, for t_{AOF} (MAX).

46. ODT turn-on time t_{AON} (MIN) is when the device leaves High-Z and ODT resistance begins to turn on. ODT turn-on time t_{AON} (MAX) is when the ODT resistance is fully on. Both are measured from t_{AOND} .
47. ODT turn-off time t_{AOF} (MIN) is when the device starts to turn off ODT resistance. ODT turn off time t_{AOF} (MAX) is when the bus is in High-Z. Both are measured from t_{AOFD} .
48. Half-clock output parameters must be derated by the actual $t_{ERR_{5per}}$ and t_{JITdty} when input clock jitter is present; this will result in each parameter becoming larger. The parameter t_{AOF} (MIN) is required to be derated by subtracting both $t_{ERR_{5per}}$ (MAX) and t_{JITdty} (MAX). The parameter t_{AOF} (MAX) is required to be derated by subtracting both $t_{ERR_{5per}}$ (MIN) and t_{JITdty} (MIN).
49. Should use 8 t_{CK} for backward compatibility.
50. DRAM devices should be evenly addressed when being accessed. Disproportionate accesses to a particular row address may result in reduction of the product lifetime.

AC and DC Operating Conditions

Table 12: Recommended DC Operating Conditions (SSTL_18)

All voltages referenced to V_{SS}

Parameter	Symbol	Min	Nom	Max	Units	Notes
Supply voltage	V_{DD}	1.7	1.8	1.9	V	1, 2
V_{DDL} supply voltage	V_{DDL}	1.7	1.8	1.9	V	2, 3
I/O supply voltage	V_{DDQ}	1.7	1.8	1.9	V	2, 3
I/O reference voltage	$V_{REF(DC)}$	$0.49 \times V_{DDQ}$	$0.50 \times V_{DDQ}$	$0.51 \times V_{DDQ}$	V	4
I/O termination voltage (system)	V_{TT}	$V_{REF(DC)} - 40$	$V_{REF(DC)}$	$V_{REF(DC)} + 40$	mV	5

- Notes:
- V_{DD} and V_{DDQ} must track each other. V_{DDQ} must be $\leq V_{DD}$.
 - $V_{SSQ} = V_{SSL} = V_{SS}$.
 - V_{DDQ} tracks with V_{DD} ; V_{DDL} tracks with V_{DD} .
 - V_{REF} is expected to equal $V_{DDQ}/2$ of the transmitting device and to track variations in the DC level of the same. Peak-to-peak noise (noncommon mode) on V_{REF} may not exceed ± 1 percent of the DC value. Peak-to-peak AC noise on V_{REF} may not exceed ± 2 percent of $V_{REF(DC)}$. This measurement is to be taken at the nearest V_{REF} bypass capacitor.
 - V_{TT} is not applied directly to the device. V_{TT} is a system supply for signal termination resistors, is expected to be set equal to V_{REF} , and must track variations in the DC level of V_{REF} .

ODT DC Electrical Characteristics

Table 13: ODT DC Electrical Characteristics

All voltages are referenced to V_{SS}

Parameter	Symbol	Min	Nom	Max	Units	Notes
R_{TT} effective impedance value for 75 Ω setting EMR (A6, A2) = 0, 1	$R_{TT1(EFF)}$	60	75	90	Ω	1, 2
R_{TT} effective impedance value for 150 Ω setting EMR (A6, A2) = 1, 0	$R_{TT2(EFF)}$	120	150	180	Ω	1, 2
R_{TT} effective impedance value for 50 Ω setting EMR (A6, A2) = 1, 1	$R_{TT3(EFF)}$	40	50	60	Ω	1, 2
Deviation of VM with respect to $V_{DDQ}/2$	ΔVM	-6	-	6	%	3

- Notes:
- $R_{TT1(EFF)}$ and $R_{TT2(EFF)}$ are determined by separately applying $V_{IH(AC)}$ and $V_{IL(DC)}$ to the ball being tested, and then measuring current, $I(V_{IH(AC)})$, and $I(V_{IL(AC)})$, respectively.

$$R_{TT(EFF)} = \frac{V_{IH(AC)} - V_{IL(AC)}}{I(V_{IH(AC)}) - I(V_{IL(AC)})}$$

- Minimum IT and AT device values are derated by six percent less when the devices operate between -40°C and 0°C (T_C).
- Measure voltage (VM) at tested ball with no load.

$$\Delta VM = \left(\frac{2 \times VM}{V_{DDQ}} - 1 \right) \times 100$$

Input Electrical Characteristics and Operating Conditions

Table 14: Input DC Logic Levels

All voltages are referenced to V_{SS}

Parameter	Symbol	Min	Max	Units
Input high (logic 1) voltage	$V_{IH(DC)}$	$V_{REF(DC)} + 125$	V_{DDQ}^1	mV
Input low (logic 0) voltage	$V_{IL(DC)}$	-300	$V_{REF(DC)} - 125$	mV

Note: 1. $V_{DDQ} + 300\text{mV}$ allowed provided 1.9V is not exceeded.

Table 15: Input AC Logic Levels

All voltages are referenced to V_{SS}

Parameter	Symbol	Min	Max	Units
Input high (logic 1) voltage (-25E/-25/-3E/-3)	$V_{IH(AC)}$	$V_{REF(DC)} + 200$	V_{DDQ}^1	mV
Input low (logic 0) voltage (-25E/-25/-3E/-3)	$V_{IL(AC)}$	-300	$V_{REF(DC)} - 200$	mV

Note: 1. Refer to (page 0).

Figure 10: Single-Ended Input Signal Levels

Note: 1. Numbers in diagram reflect nominal DDR2-400/DDR2-533 values.

Table 16: Differential Input Logic Levels

All voltages referenced to V_{SS}

Parameter	Symbol	Min	Max	Units	Notes
DC input signal voltage	$V_{IN(DC)}$	-300	V_{DDQ}	mV	1, 6
DC differential input voltage	$V_{ID(DC)}$	250	V_{DDQ}	mV	2, 6
AC differential input voltage	$V_{ID(AC)}$	500	V_{DDQ}	mV	3, 6
AC differential cross-point voltage	$V_{IX(AC)}$	$0.50 \times V_{DDQ} - 175$	$0.50 \times V_{DDQ} + 175$	mV	4
Input midpoint voltage	$V_{MP(DC)}$	850	950	mV	5

- Notes:
- $V_{IN(DC)}$ specifies the allowable DC execution of each input of differential pair such as CK, CK#, DQS, DQS#, LDQS, LDQS#, UDQS, UDQS#, and RDQS, RDQS#.
 - $V_{ID(DC)}$ specifies the input differential voltage $|V_{TR} - V_{CP}|$ required for switching, where V_{TR} is the true input (such as CK, DQS, LDQS, UDQS) level and V_{CP} is the complementary input (such as CK#, DQS#, LDQS#, UDQS#) level. The minimum value is equal to $V_{IH(DC)} - V_{IL(DC)}$. Differential input signal levels are shown in Figure 11.
 - $V_{ID(AC)}$ specifies the input differential voltage $|V_{TR} - V_{CP}|$ required for switching, where V_{TR} is the true input (such as CK, DQS, LDQS, UDQS, RDQS) level and V_{CP} is the complementary input (such as CK#, DQS#, LDQS#, UDQS#, RDQS#) level. The minimum value is equal to $V_{IH(AC)} - V_{IL(AC)}$, as shown in Table 15 (page 39).
 - The typical value of $V_{IX(AC)}$ is expected to be about $0.5 \times V_{DDQ}$ of the transmitting device and $V_{IX(AC)}$ is expected to track variations in V_{DDQ} . $V_{IX(AC)}$ indicates the voltage at which differential input signals must cross, as shown in Figure 11.
 - $V_{MP(DC)}$ specifies the input differential common mode voltage $(V_{TR} + V_{CP})/2$ where V_{TR} is the true input (CK, DQS) level and V_{CP} is the complementary input (CK#, DQS#). $V_{MP(DC)}$ is expected to be approximately $0.5 \times V_{DDQ}$.
 - $V_{DDQ} + 300\text{mV}$ allowed provided 1.9V is not exceeded.

Figure 11: Differential Input Signal Levels

- Notes:
- TR and CP may not be more positive than $V_{DDQ} + 0.3\text{V}$ or more negative than $V_{SS} - 0.3\text{V}$.
 - TR represents the CK, DQS, RDQS, LDQS, and UDQS signals; CP represents CK#, DQS#, RDQS#, LDQS#, and UDQS# signals.
 - This provides a minimum of 850mV to a maximum of 950mV and is expected to be $V_{DDQ}/2$.
 - TR and CP must cross in this region.
 - TR and CP must meet at least $V_{ID(DC)min}$ when static and is centered around $V_{MP(DC)}$.
 - TR and CP must have a minimum 500mV peak-to-peak swing.

512Mb: x8, x16 Automotive DDR2 SDRAM Input Electrical Characteristics and Operating Conditions

7. Numbers in diagram reflect nominal values ($V_{DDQ} = 1.8V$).

Output Electrical Characteristics and Operating Conditions

Table 17: Differential AC Output Parameters

Parameter	Symbol	Min	Max	Units	Notes
AC differential cross-point voltage	$V_{OX(AC)}$	$0.50 \times V_{DDQ} - 125$	$0.50 \times V_{DDQ} + 125$	mV	1

Note: 1. The typical value of $V_{OX(AC)}$ is expected to be about $0.5 \times V_{DDQ}$ of the transmitting device and $V_{OX(AC)}$ is expected to track variations in V_{DDQ} . $V_{OX(AC)}$ indicates the voltage at which differential output signals must cross.

Figure 12: Differential Output Signal Levels

Table 18: Output DC Current Drive

Parameter	Symbol	Value	Units	Notes
Output MIN source DC current	I_{OH}	-13.4	mA	1, 2, 4
Output MIN sink DC current	I_{OL}	13.4	mA	2, 3, 4

- Notes:
1. For $I_{OH(DC)}$; $V_{DDQ} = 1.7V$, $V_{OUT} = 1,420mV$. $(V_{OUT} - V_{DDQ})/I_{OH}$ must be less than 21Ω for values of V_{OUT} between V_{DDQ} and $V_{DDQ} - 280mV$.
 2. For $I_{OL(DC)}$; $V_{DDQ} = 1.7V$, $V_{OUT} = 280mV$. V_{OUT}/I_{OL} must be less than 21Ω for values of V_{OUT} between $0V$ and $280mV$.
 3. The DC value of V_{REF} applied to the receiving device is set to V_{TT} .
 4. The values of $I_{OH(DC)}$ and $I_{OL(DC)}$ are based on the conditions given in Notes 1 and 2. They are used to test device drive current capability to ensure $V_{IH,min}$ plus a noise margin and $V_{IL,max}$ minus a noise margin are delivered to an SSTL_18 receiver. The actual current values are derived by shifting the desired driver operating point (see output IV curves) along a 21Ω load line to define a convenient driver current for measurement.

Table 19: Output Characteristics

Parameter	Min	Nom	Max	Units	Notes
Output impedance	See Output Driver Characteristics (page 44)			Ω	1, 2
Pull-up and pull-down mismatch	0	–	4	Ω	1, 2, 3
Output slew rate	1.5	–	5	V/ns	1, 4, 5, 6

- Notes:
1. Absolute specifications: $0^{\circ}\text{C} \leq T_C \leq +85^{\circ}\text{C}$; $V_{DDQ} = 1.8\text{V} \pm 0.1\text{V}$, $V_{DD} = 1.8\text{V} \pm 0.1\text{V}$.
 2. Impedance measurement conditions for output source DC current: $V_{DDQ} = 1.7\text{V}$; $V_{OUT} = 1420\text{mV}$; $(V_{OUT} - V_{DDQ})/I_{OH}$ must be less than 23.4Ω for values of V_{OUT} between V_{DDQ} and $V_{DDQ} - 280\text{mV}$. The impedance measurement condition for output sink DC current: $V_{DDQ} = 1.7\text{V}$; $V_{OUT} = 280\text{mV}$; V_{OUT}/I_{OL} must be less than 23.4Ω for values of V_{OUT} between 0V and 280mV .
 3. Mismatch is an absolute value between pull-up and pull-down; both are measured at the same temperature and voltage.
 4. Output slew rate for falling and rising edges is measured between $V_{TT} - 250\text{mV}$ and $V_{TT} + 250\text{mV}$ for single-ended signals. For differential signals (DQS, DQS#), output slew rate is measured between $DQS - DQS\# = -500\text{mV}$ and $DQS\# - DQS = 500\text{mV}$. Output slew rate is guaranteed by design but is not necessarily tested on each device.
 5. The absolute value of the slew rate as measured from $V_{IL(DC)\text{max}}$ to $V_{IH(DC)\text{min}}$ is equal to or greater than the slew rate as measured from $V_{IL(AC)\text{max}}$ to $V_{IH(AC)\text{min}}$. This is guaranteed by design and characterization.
 6. IT and AT devices require an additional 0.4 V/ns in the MAX limit when T_C is between -40°C and 0°C .

Table 27: AC Input Test Conditions

Parameter	Symbol	Min	Max	Units	Notes
Input setup timing measurement reference level address balls, bank address balls, CS#, RAS#, CAS#, WE#, ODT, DM, UDM, LDM, and CKE	V_{RS}	See Note 2			1, 2, 3, 4

Table 27: AC Input Test Conditions (Continued)

Parameter	Symbol	Min	Max	Units	Notes
Input hold timing measurement reference level address balls, bank address balls, CS#, RAS#, CAS#, WE#, ODT, DM, UDM, LDM, and CKE	V_{RH}	See Note 5			1, 3, 4, 5
Input timing measurement reference level (single-ended) DQS for x8; UDQS, LDQS for x16	$V_{REF(DC)}$	$V_{DDQ} \times 0.49$	$V_{DDQ} \times 0.51$	V	1, 3, 4, 6
Input timing measurement reference level (differential) CK, CK# for x8, x16; DQS, DQS# for x8; RDQS, RDQS# for x8; UDQS, UDQS#, LDQS, LDQS# for x16	V_{RD}	$V_{IX(AC)}$		V	1, 3, 7, 8, 9

- Notes:
1. All voltages referenced to V_{SS} .
 2. Input waveform setup timing (t_{ISb}) is referenced from the input signal crossing at the $V_{IH(AC)}$ level for a rising signal and $V_{IL(AC)}$ for a falling signal applied to the device under test, as shown in Figure 29 (page 62).
 3. See Input Slew Rate Derating (page 51).
 4. The slew rate for single-ended inputs is measured from DC level to AC level, $V_{IL(DC)}$ to $V_{IH(AC)}$ on the rising edge and $V_{IL(AC)}$ to $V_{IH(DC)}$ on the falling edge. For signals referenced to V_{REF} , the valid intersection is where the "tangent" line intersects V_{REF} , as shown in Figure 22 (page 54), Figure 24 (page 55), Figure 26 (page 60), and Figure 28 (page 61).
 5. Input waveform hold (t_{IHb}) timing is referenced from the input signal crossing at the $V_{IL(DC)}$ level for a rising signal and $V_{IH(DC)}$ for a falling signal applied to the device under test, as shown in Figure 29 (page 62).
 6. Input waveform setup timing (t_{DS}) and hold timing (t_{DH}) for single-ended data strobe is referenced from the crossing of DQS, UDQS, or LDQS through the V_{ref} level applied to the device under test, as shown in Figure 31 (page 63).
 7. Input waveform setup timing (t_{DS}) and hold timing (t_{DH}) when differential data strobe is enabled is referenced from the cross-point of DQS/DQS#, UDQS/UDQS#, or LDQS/LDQS#, as shown in Figure 30 (page 62).
 8. Input waveform timing is referenced to the crossing point level (V_{IX}) of two input signals (V_{TR} and V_{CP}) applied to the device under test, where V_{TR} is the true input signal and V_{CP} is the complementary input signal, as shown in Figure 32 (page 63).
 9. The slew rate for differentially ended inputs is measured from twice the DC level to twice the AC level: $2 \times V_{IL(DC)}$ to $2 \times V_{IH(AC)}$ on the rising edge and $2 \times V_{IL(AC)}$ to $2 \times V_{IH(DC)}$ on the falling edge. For example, the CK/CK# would be -250mV to 500mV for CK rising edge and would be 250mV to -500mV for CK falling edge.

Input Slew Rate Derating

For all input signals, the total t_{IS} (setup time) and t_{IH} (hold time) required is calculated by adding the data sheet t_{IS} (base) and t_{IH} (base) value to the Δt_{IS} and Δt_{IH} derating value, respectively. Example: t_{IS} (total setup time) = t_{IS} (base) + Δt_{IS} .

t_{IS} , the nominal slew rate for a rising signal, is defined as the slew rate between the last crossing of $V_{REF(DC)}$ and the first crossing of $V_{IH(AC)min}$. Setup nominal slew rate (t_{IS}) for a falling signal is defined as the slew rate between the last crossing of $V_{REF(DC)}$ and the first crossing of $V_{IL(AC)max}$.

If the actual signal is always earlier than the nominal slew rate line between shaded “ $V_{REF(DC)}$ to AC region,” use the nominal slew rate for the derating value (Figure 21 (page 54)).

If the actual signal is later than the nominal slew rate line anywhere between the shaded “ $V_{REF(DC)}$ to AC region,” the slew rate of a tangent line to the actual signal from the AC level to DC level is used for the derating value (see Figure 22 (page 54)).

t_{IH} , the nominal slew rate for a rising signal, is defined as the slew rate between the last crossing of $V_{IL(DC)max}$ and the first crossing of $V_{REF(DC)}$. t_{IH} , nominal slew rate for a falling signal, is defined as the slew rate between the last crossing of $V_{IH(DC)min}$ and the first crossing of $V_{REF(DC)}$.

If the actual signal is always later than the nominal slew rate line between shaded “DC to $V_{REF(DC)}$ region,” use the nominal slew rate for the derating value (Figure 23 (page 55)).

If the actual signal is earlier than the nominal slew rate line anywhere between shaded “DC to $V_{REF(DC)}$ region,” the slew rate of a tangent line to the actual signal from the DC level to $V_{REF(DC)}$ level is used for the derating value (Figure 24 (page 55)).

Although the total setup time might be negative for slow slew rates (a valid input signal will not have reached $V_{IH(AC)}/V_{IL(AC)}$ at the time of the rising clock transition), a valid input signal is still required to complete the transition and reach $V_{IH(AC)}/V_{IL(AC)}$.

For slew rates in between the values listed in Table 28 (page 52) and Table 29 (page 53), the derating values may be obtained by linear interpolation.

- Notes:
- For all input signals, the total t_{DS} and t_{DH} required is calculated by adding the data sheet value to the derating value listed in Table 30.
 - t_{DS} nominal slew rate for a rising signal is defined as the slew rate between the last crossing of $V_{REF(DC)}$ and the first crossing of $V_{IH(AC)min}$. t_{DS} nominal slew rate for a falling signal is defined as the slew rate between the last crossing of $V_{REF(DC)}$ and the first crossing of $V_{IL(AC)max}$. If the actual signal is always earlier than the nominal slew rate line between the shaded " $V_{REF(DC)}$ to AC region," use the nominal slew rate for the derating value (see Figure 25 (page 60)). If the actual signal is later than the nominal slew rate line anywhere between the shaded " $V_{REF(DC)}$ to AC region," the slew rate of a tangent line to the actual signal from the AC level to DC level is used for the derating value (see Figure 26 (page 60)).
 - t_{DH} nominal slew rate for a rising signal is defined as the slew rate between the last crossing of $V_{IL(DC)max}$ and the first crossing of $V_{REF(DC)}$. t_{DH} nominal slew rate for a falling signal is defined as the slew rate between the last crossing of $V_{IH(DC)min}$ and the first crossing of $V_{REF(DC)}$. If the actual signal is always later than the nominal slew rate line between the shaded "DC level to $V_{REF(DC)}$ region," use the nominal slew rate for the derating value (see Figure 27 (page 61)). If the actual signal is earlier than the nominal slew rate line anywhere between shaded "DC to $V_{REF(DC)}$ region," the slew rate of a tangent line to the actual signal from the DC level to $V_{REF(DC)}$ level is used for the derating value (see Figure 28 (page 61)).
 - Although the total setup time might be negative for slow slew rates (a valid input signal will not have reached $V_{IH(AC)}/V_{IL(AC)}$ at the time of the rising clock transition), a valid input signal is still required to complete the transition and reach $V_{IH(AC)}/V_{IL(AC)}$.
 - For slew rates between the values listed in this table, the derating values may be obtained by linear interpolation.
 - These values are typically not subject to production test. They are verified by design and characterization.
 - Single-ended DQS requires special derating. The values in Table 32 (page 58) are the DQS single-ended slew rate derating with DQS referenced at V_{REF} and DQ referenced at the logic levels t_{DS_b} and t_{DH_b} . Converting the derated base values from DQ referenced to the AC/DC trip points to DQ referenced to V_{REF} is listed in Table 34 (page 59) and Table 35 (page 59). Table 34 provides the V_{REF} -based fully derated values for the DQ (t_{DS_a} and t_{DH_a}) for DDR2-533. Table 35 provides the V_{REF} -based fully derated values for the DQ (t_{DS_a} and t_{DH_a}) for DDR2-400.

- Notes:
- For all input signals the total t_{DS} and t_{DH} required is calculated by adding the data sheet value to the derating value listed in Table 31.
 - t_{DS} nominal slew rate for a rising signal is defined as the slew rate between the last crossing of $V_{REF(DC)}$ and the first crossing of $V_{IH(AC)min}$. t_{DS} nominal slew rate for a falling signal is defined as the slew rate between the last crossing of $V_{REF(DC)}$ and the first crossing of $V_{IL(AC)max}$. If the actual signal is always earlier than the nominal slew rate line between the shaded " $V_{REF(DC)}$ to AC region," use the nominal slew rate for the derating value (see Figure 25 (page 60)). If the actual signal is later than the nominal slew rate line anywhere between shaded " $V_{REF(DC)}$ to AC region," the slew rate of a tangent line to the actual signal from the AC level to DC level is used for the derating value (see Figure 26 (page 60)).
 - t_{DH} nominal slew rate for a rising signal is defined as the slew rate between the last crossing of $V_{IL(DC)max}$ and the first crossing of $V_{REF(DC)}$. t_{DH} nominal slew rate for a falling signal is defined as the slew rate between the last crossing of $V_{IH(DC)min}$ and the first crossing of $V_{REF(DC)}$. If the actual signal is always later than the nominal slew rate line between the shaded "DC level to $V_{REF(DC)}$ region," use the nominal slew rate for the derating value (see Figure 27 (page 61)). If the actual signal is earlier than the nominal slew rate line anywhere between the shaded "DC to $V_{REF(DC)}$ region," the slew rate of a tangent line to the actual signal from the DC level to $V_{REF(DC)}$ level is used for the derating value (see Figure 28 (page 61)).
 - Although the total setup time might be negative for slow slew rates (a valid input signal will not have reached $V_{IH(AC)}/V_{IL(AC)}$ at the time of the rising clock transition), a valid input signal is still required to complete the transition and reach $V_{IH(AC)}/V_{IL(AC)}$.
 - For slew rates between the values listed in this table, the derating values may be obtained by linear interpolation.
 - These values are typically not subject to production test. They are verified by design and characterization.
 - Single-ended DQS requires special derating. The values in Table 32 (page 58) are the DQS single-ended slew rate derating with DQS referenced at V_{REF} and DQ referenced at the logic levels t_{DSb} and t_{DHb} . Converting the derated base values from DQ referenced to the AC/DC trip points to DQ referenced to V_{REF} is listed in Table 33 (page 58). Table 33 provides the V_{REF} -based fully derated values for the DQ (t_{DSa} and t_{DHa}) for

512Mb: x8, x16 Automotive DDR2 SDRAM Input Slew Rate Derating

DDR2-667. It is not advised to operate DDR2-800 and DDR2-1066 devices with single-ended DQS; however, Table 32 would be used with the base values.

Table 32: Single-Ended DQS Slew Rate Derating Values Using t_{DS_b} and t_{DH_b}

Reference points indicated in bold; Derating values are to be used with base t_{DS_b} - and t_{DH_b} -specified values

- Notes:
1. All DDR2 SDRAM commands are defined by states of CS#, RAS#, CAS#, WE#, and CKE at the rising edge of the clock.
 2. The state of ODT does not affect the states described in this table. The ODT function is not available during self refresh. See ODT Timing (page 121) for details.
 3. "X" means "H or L" (but a defined logic level) for valid I_{DD} measurements.
 4. BA2 is only applicable for densities ≥1Gb.
 5. An *n* is the most significant address bit for a given density and configuration. Some larger address bits may be "Don't Care" during column addressing, depending on density and configuration.

6. Bank addresses (BA) determine which bank is to be operated upon. BA during a LOAD MODE command selects which mode register is programmed.
7. SELF REFRESH exit is asynchronous.
8. Burst reads or writes at BL = 4 cannot be terminated or interrupted. See (page 0) and Figure 58 (page 101) for other restrictions and details.
9. The power-down mode does not perform any REFRESH operations. The duration of power-down is limited by the refresh requirements outlined in the AC parametric section.

Table 37: Truth Table – Current State Bank *n* – Command to Bank *n*

Notes: 1–6 apply to the entire table

Current State	CS#	RAS#	CAS#	WE#	Command/Action	Notes
Any	H	X	X	X	DESELECT (NOP/continue previous operation)	
	L	H	H	H	NO OPERATION (NOP/continue previous operation)	
Idle	L	L	H	H	ACTIVATE (select and activate row)	
	L	L	L	H	REFRESH	7
	L	L	L	L	LOAD MODE	7
Row active	L	H	L	H	READ (select column and start READ burst)	8
	L	H	L	L	WRITE (select column and start WRITE burst)	8
	L	L	H	L	PRECHARGE (deactivate row in bank or banks)	9
Read (auto precharge disabled)	L	H	L	H	READ (select column and start new READ burst)	8
	L	H	L	L	WRITE (select column and start WRITE burst)	8, 10
	L	L	H	L	PRECHARGE (start PRECHARGE)	9
Write (auto pre-charge disabled)	L	H	L	H	READ (select column and start READ burst)	8
	L	H	L	L	WRITE (select column and start new WRITE burst)	8
	L	L	H	L	PRECHARGE (start PRECHARGE)	9

- Notes:
1. This table applies when CKEn - 1 was HIGH and CKEn is HIGH and after ^tXSNR has been met (if the previous state was self refresh).
 2. This table is bank-specific, except where noted (the current state is for a specific bank and the commands shown are those allowed to be issued to that bank when in that state). Exceptions are covered in the notes below.
 3. Current state definitions:

Idle: The bank has been precharged, ^tRP has been met, and any READ burst is complete.

Row active: A row in the bank has been activated, and ^tRCD has been met. No data bursts/ accesses and no register accesses are in progress.

Read: A READ burst has been initiated, with auto precharge disabled and has not yet terminated.

Write: A WRITE burst has been initiated with auto precharge disabled and has not yet terminated.

4. The following states must not be interrupted by a command issued to the same bank. Issue Deselect or NOP commands, or allowable commands to the other bank, on any clock edge occurring during these states. Allowable commands to the other bank are determined by its current state and this table, and according to Table 38 (page 67).

- | | |
|---|---|
| Precharge: | Starts with registration of a PRECHARGE command and ends when t_{RP} is met. After t_{RP} is met, the bank will be in the idle state. |
| Read with auto precharge enabled: | Starts with registration of a READ command with auto precharge enabled and ends when t_{RP} has been met. After t_{RP} is met, the bank will be in the idle state. |
| Row activate: | Starts with registration of an ACTIVATE command and ends when t_{RCD} is met. After t_{RCD} is met, the bank will be in the row active state. |
| Write with auto precharge enabled: | Starts with registration of a WRITE command with auto precharge enabled and ends when t_{RP} has been met. After t_{RP} is met, the bank will be in the idle state. |
5. The following states must not be interrupted by any executable command (DESELECT or NOP commands must be applied on each positive clock edge during these states):

Refresh:	Starts with registration of a REFRESH command and ends when t_{RFC} is met. After t_{RFC} is met, the DDR2 SDRAM will be in the all banks idle state.
Accessing mode register:	Starts with registration of the LOAD MODE command and ends when t_{MRD} has been met. After t_{MRD} is met, the DDR2 SDRAM will be in the all banks idle state.
Precharge all:	Starts with registration of a PRECHARGE ALL command and ends when t_{RP} is met. After t_{RP} is met, all banks will be in the idle state.
 6. All states and sequences not shown are illegal or reserved.
 7. Not bank-specific; requires that all banks are idle and bursts are not in progress.
 8. READs or WRITEs listed in the Command/Action column include READs or WRITEs with auto precharge enabled and READs or WRITEs with auto precharge disabled.
 9. May or may not be bank-specific; if multiple banks are to be precharged, each must be in a valid state for precharging.
 10. A WRITE command may be applied after the completion of the READ burst.

Table 38: Truth Table – Current State Bank *n* – Command to Bank *m*

Notes: 1–6 apply to the entire table

Current State	CS#	RAS#	CAS#	WE#	Command/Action	Notes
Any	H	X	X	X	DESELECT (NOP/continue previous operation)	
	L	H	H	H	NO OPERATION (NOP/continue previous operation)	
Idle	X	X	X	X	Any command otherwise allowed to bank <i>m</i>	
Row active, active, or precharge	L	L	H	H	ACTIVATE (select and activate row)	
	L	H	L	H	READ (select column and start READ burst)	7
	L	H	L	L	WRITE (select column and start WRITE burst)	7
	L	L	H	L	PRECHARGE	
Read (auto precharge disabled)	L	L	H	H	ACTIVATE (select and activate row)	
	L	H	L	H	READ (select column and start new READ burst)	7
	L	H	L	L	WRITE (select column and start WRITE burst)	7, 8
	L	L	H	L	PRECHARGE	
Write (auto precharge disabled)	L	L	H	H	ACTIVATE (select and activate row)	
	L	H	L	H	READ (select column and start READ burst)	7, 9, 10
	L	H	L	L	WRITE (select column and start new WRITE burst)	7
	L	L	H	L	PRECHARGE	
Read (with auto precharge)	L	L	H	H	ACTIVATE (select and activate row)	
	L	H	L	H	READ (select column and start new READ burst)	7
	L	H	L	L	WRITE (select column and start WRITE burst)	7, 8
	L	L	H	L	PRECHARGE	
Write (with auto precharge)	L	L	H	H	ACTIVATE (select and activate row)	
	L	H	L	H	READ (select column and start READ burst)	7, 10
	L	H	L	L	WRITE (select column and start new WRITE burst)	7
	L	L	H	L	PRECHARGE	

- Notes:
1. This table applies when $\overline{\text{CKEn}} - 1$ was HIGH and $\overline{\text{CKEn}}$ is HIGH and after $^t\text{XSNR}$ has been met (if the previous state was self refresh).
 2. This table describes an alternate bank operation, except where noted (the current state is for bank *n* and the commands shown are those allowed to be issued to bank *m*, assuming that bank *m* is in such a state that the given command is allowable). Exceptions are covered in the notes below.
 3. Current state definitions:

Idle:	The bank has been precharged, ^tRP has been met, and any READ burst is complete.
Row active:	A row in the bank has been activated and ^tRCD has been met. No data bursts/accesses and no register accesses are in progress.
Read:	A READ burst has been initiated with auto precharge disabled and has not yet terminated.
Write:	A WRITE burst has been initiated with auto precharge disabled and has not yet terminated.

**READ with auto precharge enabled/
WRITE with auto precharge enabled:**

The READ with auto precharge enabled or WRITE with auto precharge enabled states can each be broken into two parts: the access period and the precharge period. For READ with auto precharge, the precharge period is defined as if the same burst was executed with auto precharge disabled and then followed with the earliest possible PRECHARGE command that still accesses all of the data in the burst. For WRITE with auto precharge, the precharge period begins when t_{WR} ends, with t_{WR} measured as if auto precharge was disabled. The access period starts with registration of the command and ends where the precharge period (or t_{RP}) begins. This device supports concurrent auto precharge such that when a READ with auto precharge is enabled or a WRITE with auto precharge is enabled, any command to other banks is allowed, as long as that command does not interrupt the read or write data transfer already in process. In either case, all other related limitations apply (contention between read data and write data must be avoided).

The minimum delay from a READ or WRITE command with auto precharge enabled to a command to a different bank is summarized in Table 39 (page 68).

4. REFRESH and LOAD MODE commands may only be issued when all banks are idle.
5. Not used.
6. All states and sequences not shown are illegal or reserved.
7. READs or WRITEs listed in the Command/Action column include READs or WRITEs with auto precharge enabled and READs or WRITEs with auto precharge disabled.
8. A WRITE command may be applied after the completion of the READ burst.
9. Requires appropriate DM.
10. The number of clock cycles required to meet t_{WTR} is either two or t_{WTR}/t_{CK} , whichever is greater.

Table 39: Minimum Delay with Auto Precharge Enabled

From Command (Bank <i>n</i>)	To Command (Bank <i>m</i>)	Minimum Delay (with Concurrent Auto Precharge)	Units
WRITE with auto precharge	READ or READ with auto precharge	$(CL - 1) + (BL/2) + t_{WTR}$	t_{CK}
	WRITE or WRITE with auto precharge	$(BL/2)$	t_{CK}
	PRECHARGE or ACTIVATE	1	t_{CK}
READ with auto precharge	READ or READ with auto precharge	$(BL/2)$	t_{CK}
	WRITE or WRITE with auto precharge	$(BL/2) + 2$	t_{CK}
	PRECHARGE or ACTIVATE	1	t_{CK}

DESELECT

The Deselect function (CS# HIGH) prevents new commands from being executed by the DDR2 SDRAM. The DDR2 SDRAM is effectively deselected. Operations already in progress are not affected. Deselect is also referred to as COMMAND INHIBIT.

NO OPERATION (NOP)

The NO OPERATION (NOP) command is used to instruct the selected DDR2 SDRAM to perform a NOP (CS# is LOW; RAS#, CAS#, and WE are HIGH). This prevents unwanted commands from being registered during idle or wait states. Operations already in progress are not affected.

LOAD MODE (LM)

The mode registers are loaded via bank address and address inputs. The bank address balls determine which mode register will be programmed. See Mode Register (MR) (page 70). The LM command can only be issued when all banks are idle, and a subsequent executable command cannot be issued until t_{MRD} is met.

ACTIVATE

The ACTIVATE command is used to open (or activate) a row in a particular bank for a subsequent access. The value on the bank address inputs determines the bank, and the address inputs select the row. This row remains active (or open) for accesses until a precharge command is issued to that bank. A precharge command must be issued before opening a different row in the same bank.

READ

The READ command is used to initiate a burst read access to an active row. The value on the bank address inputs determine the bank, and the address provided on address inputs A0–A_i (where A_i is the most significant column address bit for a given configuration) selects the starting column location. The value on input A10 determines whether or not auto precharge is used. If auto precharge is selected, the row being accessed will be precharged at the end of the read burst; if auto precharge is not selected, the row will remain open for subsequent accesses.

DDR2 SDRAM also supports the AL feature, which allows a READ or WRITE command to be issued prior to t_{RCD} (MIN) by delaying the actual registration of the READ/WRITE command to the internal device by AL clock cycles.

WRITE

The WRITE command is used to initiate a burst write access to an active row. The value on the bank select inputs selects the bank, and the address provided on inputs A0–A_i (where A_i is the most significant column address bit for a given configuration) selects the starting column location. The value on input A10 determines whether or not auto precharge is used. If auto precharge is selected, the row being accessed will be precharged at the end of the WRITE burst; if auto precharge is not selected, the row will remain open for subsequent accesses.

DDR2 SDRAM also supports the AL feature, which allows a READ or WRITE command to be issued prior to t_{RCD} (MIN) by delaying the actual registration of the READ/WRITE command to the internal device by AL clock cycles.

Input data appearing on the DQ is written to the memory array subject to the DM input logic level appearing coincident with the data. If a given DM signal is registered LOW, the corresponding data will be written to memory; if the DM signal is registered HIGH, the corresponding data inputs will be ignored, and a WRITE will not be executed to that byte/column location (see Figure 63 (page 106)).

PRECHARGE

The PRECHARGE command is used to deactivate the open row in a particular bank or the open row in all banks. The bank(s) will be available for a subsequent row activation a specified time ('RP) after the PRECHARGE command is issued, except in the case of concurrent auto precharge, where a READ or WRITE command to a different bank is allowed as long as it does not interrupt the data transfer in the current bank and does not violate any other timing parameters. After a bank has been precharged, it is in the idle state and must be activated prior to any READ or WRITE commands being issued to that bank. A PRECHARGE command is allowed if there is no open row in that bank (idle state) or if the previously open row is already in the process of precharging. However, the precharge period will be determined by the last PRECHARGE command issued to the bank.

REFRESH

REFRESH is used during normal operation of the DDR2 SDRAM and is analogous to CAS#-before-RAS# (CBR) REFRESH. All banks must be in the idle mode prior to issuing a REFRESH command. This command is nonpersistent, so it must be issued each time a refresh is required. The addressing is generated by the internal refresh controller. This makes the address bits a "Don't Care" during a REFRESH command.

SELF REFRESH

The SELF REFRESH command can be used to retain data in the DDR2 SDRAM, even if the rest of the system is powered down. When in the self refresh mode, the DDR2 SDRAM retains data without external clocking. All power supply inputs (including Vref) must be maintained at valid levels upon entry/exit *and* during SELF REFRESH operation.

The SELF REFRESH command is initiated like a REFRESH command except CKE is LOW. The DLL is automatically disabled upon entering self refresh and is automatically enabled upon exiting self refresh.

Mode Register (MR)

The mode register is used to define the specific mode of operation of the DDR2 SDRAM. This definition includes the selection of a burst length, burst type, CAS latency, operating mode, DLL RESET, write recovery, and power-down mode, as shown in Figure 33 (page 71). Contents of the mode register can be altered by re-executing the LOAD MODE (LM) command. If the user chooses to modify only a subset of the MR variables, all variables must be programmed when the command is issued.

The MR is programmed via the LM command and will retain the stored information until it is programmed again or until the device loses power (except for bit M8, which is self-clearing). Reprogramming the mode register will not alter the contents of the memory array, provided it is performed correctly.

The LM command can only be issued (or reissued) when all banks are in the precharged state (idle state) and no bursts are in progress. The controller must wait the specified time 'MRD before initiating any subsequent operations such as an ACTIVATE command. Violating either of these requirements will result in an unspecified operation.

Burst Length

Burst length is defined by bits M0–M2, as shown in Figure 33. Read and write accesses to the DDR2 SDRAM are burst-oriented, with the burst length being programmable to either four or eight. The burst length determines the maximum number of column locations that can be accessed for a given READ or WRITE command.

When a READ or WRITE command is issued, a block of columns equal to the burst length is effectively selected. All accesses for that burst take place within this block, meaning that the burst will wrap within the block if a boundary is reached. The block is uniquely selected by A2–A_i when BL = 4 and by A3–A_i when BL = 8 (where A_i is the most significant column address bit for a given configuration). The remaining (least significant) address bit(s) is (are) used to select the starting location within the block. The programmed burst length applies to both read and write bursts.

Figure 33: MR Definition

- Notes:
1. M16 (BA2) is only applicable for densities ≥1Gb, reserved for future use, and must be programmed to "0."
 2. Mode bits (M_n) with corresponding address balls (A_n) greater than M12 (A12) are reserved for future use and must be programmed to "0."
 3. Not all listed WR and CL options are supported in any individual speed grade.

Burst Type

Accesses within a given burst may be programmed to be either sequential or interleaved. The burst type is selected via bit M3, as shown in Figure 33. The ordering of accesses within a burst is determined by the burst length, the burst type, and the starting column address, as shown in Table 40. DDR2 SDRAM supports 4-bit burst mode and 8-bit burst mode only. For 8-bit burst mode, full interleaved address ordering is supported; however, sequential address ordering is nibble-based.

Table 40: Burst Definition

Burst Length	Starting Column Address (A2, A1, A0)	Order of Accesses Within a Burst	
		Burst Type = Sequential	Burst Type = Interleaved
4	0 0 0	0, 1, 2, 3	0, 1, 2, 3
	0 0 1	1, 2, 3, 0	1, 0, 3, 2
	0 1 0	2, 3, 0, 1	2, 3, 0, 1
	0 1 1	3, 0, 1, 2	3, 2, 1, 0
8	0 0 0	0, 1, 2, 3, 4, 5, 6, 7	0, 1, 2, 3, 4, 5, 6, 7
	0 0 1	1, 2, 3, 0, 5, 6, 7, 4	1, 0, 3, 2, 5, 4, 7, 6
	0 1 0	2, 3, 0, 1, 6, 7, 4, 5	2, 3, 0, 1, 6, 7, 4, 5
	0 1 1	3, 0, 1, 2, 7, 4, 5, 6	3, 2, 1, 0, 7, 6, 5, 4
	1 0 0	4, 5, 6, 7, 0, 1, 2, 3	4, 5, 6, 7, 0, 1, 2, 3
	1 0 1	5, 6, 7, 4, 1, 2, 3, 0	5, 4, 7, 6, 1, 0, 3, 2
	1 1 0	6, 7, 4, 5, 2, 3, 0, 1	6, 7, 4, 5, 2, 3, 0, 1
	1 1 1	7, 4, 5, 6, 3, 0, 1, 2	7, 6, 5, 4, 3, 2, 1, 0

Operating Mode

The normal operating mode is selected by issuing a command with bit M7 set to “0,” and all other bits set to the desired values, as shown in Figure 33 (page 71). When bit M7 is “1,” no other bits of the mode register are programmed. Programming bit M7 to “1” places the DDR2 SDRAM into a test mode that is only used by the manufacturer and should *not* be used. No operation or functionality is guaranteed if M7 bit is “1.”

DLL RESET

DLL RESET is defined by bit M8, as shown in Figure 33. Programming bit M8 to “1” will activate the DLL RESET function. Bit M8 is self-clearing, meaning it returns back to a value of “0” after the DLL RESET function has been issued.

Anytime the DLL RESET function is used, 200 clock cycles must occur before a READ command can be issued to allow time for the internal clock to be synchronized with the external clock. Failing to wait for synchronization to occur may result in a violation of the t_{AC} or t_{DQSCK} parameters.

Write Recovery

Write recovery (WR) time is defined by bits M9–M11, as shown in Figure 33 (page 71). The WR register is used by the DDR2 SDRAM during WRITE with auto precharge operation. During WRITE with auto precharge operation, the DDR2 SDRAM delays the internal auto precharge operation by WR clocks (programmed in bits M9–M11) from the last data burst. An example of WRITE with auto precharge is shown in Figure 62 (page 105).

WR values of 2, 3, 4, 5, 6, 7, or 8 clocks may be used for programming bits M9–M11. The user is required to program the value of WR, which is calculated by dividing t_{WR} (in nanoseconds) by t_{CK} (in nanoseconds) and rounding up a noninteger value to the next integer; $WR (\text{cycles}) = t_{WR} (\text{ns}) / t_{CK} (\text{ns})$. Reserved states should not be used as an unknown operation or incompatibility with future versions may result.

Power-Down Mode

Active power-down (PD) mode is defined by bit M12, as shown in Figure 33. PD mode enables the user to determine the active power-down mode, which determines performance versus power savings. PD mode bit M12 does not apply to precharge PD mode.

When bit M12 = 0, standard active PD mode, or “fast-exit” active PD mode, is enabled. The t_{XARD} parameter is used for fast-exit active PD exit timing. The DLL is expected to be enabled and running during this mode.

When bit M12 = 1, a lower-power active PD mode, or “slow-exit” active PD mode, is enabled. The t_{XARDS} parameter is used for slow-exit active PD exit timing. The DLL can be enabled but “frozen” during active PD mode because the exit-to-READ command timing is relaxed. The power difference expected between I_{DD3P} normal and I_{DD3P} low-power mode is defined in the DDR2 I_{DD} Specifications and Conditions table.

CAS Latency (CL)

The CAS latency (CL) is defined by bits M4–M6, as shown in Figure 33 (page 71). CL is the delay, in clock cycles, between the registration of a READ command and the availability of the first bit of output data. The CL can be set to 3, 4, 5, 6, or 7 clocks, depending on the speed grade option being used.

DDR2 SDRAM does not support any half-clock latencies. Reserved states should not be used as an unknown operation otherwise incompatibility with future versions may result.

DDR2 SDRAM also supports a feature called posted CAS additive latency (AL). This feature allows the READ command to be issued prior to $t_{RCD}(\text{MIN})$ by delaying the internal command to the DDR2 SDRAM by AL clocks. The AL feature is described in further detail in Posted CAS Additive Latency (AL) (page 77).

Examples of CL = 3 and CL = 4 are shown in Figure 34; both assume AL = 0. If a READ command is registered at clock edge n , and the CL is m clocks, the data will be available nominally coincident with clock edge $n + m$ (this assumes AL = 0).

Figure 34: CL

- Notes:
1. BL = 4.
 2. Posted CAS# additive latency (AL) = 0.
 3. Shown with nominal t_{AC} , t_{DQSCK} , and t_{DQSQ} .

Extended Mode Register (EMR)

The extended mode register controls functions beyond those controlled by the mode register; these additional functions are DLL enable/disable, output drive strength, on-die termination (ODT), posted AL, off-chip driver impedance calibration (OCD), DQS# enable/disable, RDQS/RDQS# enable/disable, and output disable/enable. These functions are controlled via the bits shown in Figure 35. The EMR is programmed via the LM command and will retain the stored information until it is programmed again or the device loses power. Reprogramming the EMR will not alter the contents of the memory array, provided it is performed correctly.

The EMR must be loaded when all banks are idle and no bursts are in progress, and the controller must wait the specified time t_{MRD} before initiating any subsequent operation. Violating either of these requirements could result in an unspecified operation.

Figure 35: EMR Definition

- Notes:
1. E16 (BA2) is only applicable for densities $\geq 1\text{Gb}$, reserved for future use, and must be programmed to 0.
 2. Mode bits (E_n) with corresponding address balls (A_n) greater than E12 (A12) are reserved for future use and must be programmed to 0.
 3. Not all listed AL options are supported in any individual speed grade.
 4. As detailed in the Initialization section notes, during initialization of the OCD operation, all three bits must be set to 1 for the OCD default state, then set to 0 before initialization is finished.

DLL Enable/Disable

The DLL may be enabled or disabled by programming bit E0 during the LM command, as shown in Figure 35 (page 75). These specifications are applicable when the DLL is enabled for normal operation. DLL enable is required during power-up initialization and upon returning to normal operation after having disabled the DLL for the purpose of debugging or evaluation. Enabling the DLL should always be followed by resetting the DLL using the LM command.

The DLL is automatically disabled when entering SELF REFRESH operation and is automatically re-enabled and reset upon exit of SELF REFRESH operation.

Anytime the DLL is enabled (and subsequently reset), 200 clock cycles must occur before a READ command can be issued to allow time for the internal clock to synchronize with the external clock. Failing to wait for synchronization to occur may result in a violation of the t_{AC} or t_{DQSCK} parameters.

Anytime the DLL is disabled and the device is operated below 25 MHz, any AUTO REFRESH command should be followed by a PRECHARGE ALL command.

Output Drive Strength

The output drive strength is defined by bit E1, as shown in Figure 35. The normal drive strength for all outputs is specified to be SSTL_18. Programming bit E1 = 0 selects normal (full strength) drive strength for all outputs. Selecting a reduced drive strength option (E1 = 1) will reduce all outputs to approximately 45 to 60 percent of the SSTL_18 drive strength. This option is intended for the support of lighter load and/or point-to-point environments.

DQS# Enable/Disable

The DQS# ball is enabled by bit E10. When E10 = 0, DQS# is the complement of the differential data strobe pair DQS/DQS#. When disabled (E10 = 1), DQS is used in a single-ended mode and the DQS# ball is disabled. When disabled, DQS# should be left floating; however, it may be tied to ground via a 20 Ω to 10k Ω resistor. This function is also used to enable/disable RDQS#. If RDQS is enabled (E11 = 1) and DQS# is enabled (E10 = 0), then both DQS# and RDQS# will be enabled.

RDQS Enable/Disable

The RDQS ball is enabled by bit E11, as shown in Figure 35. This feature is only applicable to the x8 configuration. When enabled (E11 = 1), RDQS is identical in function and timing to data strobe DQS during a READ. During a WRITE operation, RDQS is ignored by the DDR2 SDRAM.

Output Enable/Disable

The OUTPUT ENABLE function is defined by bit E12, as shown in Figure 35. When enabled (E12 = 0), all outputs (DQ, DQS, DQS#, RDQS, RDQS#) function normally. When disabled (E12 = 1), all outputs (DQ, DQS, DQS#, RDQS, RDQS#) are disabled, thus removing output buffer current. The output disable feature is intended to be used during I_{DD} characterization of read current.

On-Die Termination (ODT)

ODT effective resistance, $R_{TT(EFF)}$, is defined by bits E2 and E6 of the EMR, as shown in Figure 35 (page 75). The ODT feature is designed to improve signal integrity of the memory channel by allowing the DDR2 SDRAM controller to independently turn on/off ODT for any or all devices. R_{TT} effective resistance values of 50Ω, 75Ω, and 150Ω are selectable and apply to each DQ, DQS/DQS#, RDQS/RDQS#, UDQS/UDQS#, LDQS/LDQS#, DM, and UDM/LDM signal. Bits (E6, E2) determine what ODT resistance is enabled by turning on/off sw1, sw2, or sw3. The ODT effective resistance value is selected by enabling switch sw1, which enables all R1 values that are 150Ω each, enabling an effective resistance of 75Ω ($R_{TT2(EFF)} = R2/2$). Similarly, if sw2 is enabled, all R2 values that are 300Ω each, enable an effective ODT resistance of 150Ω ($R_{TT2(EFF)} = R2/2$). Switch sw3 enables R1 values of 100Ω, enabling effective resistance of 50Ω. Reserved states should not be used, as an unknown operation or incompatibility with future versions may result.

The ODT control ball is used to determine when $R_{TT(EFF)}$ is turned on and off, assuming ODT has been enabled via bits E2 and E6 of the EMR. The ODT feature and ODT input ball are only used during active, active power-down (both fast-exit and slow-exit modes), and precharge power-down modes of operation.

ODT must be turned off prior to entering self refresh mode. During power-up and initialization of the DDR2 SDRAM, ODT should be disabled until the EMR command is issued. This will enable the ODT feature, at which point the ODT ball will determine the $R_{TT(EFF)}$ value. Anytime the EMR enables the ODT function, ODT may not be driven HIGH until eight clocks after the EMR has been enabled (see Figure 78 (page 122) for ODT timing diagrams).

Off-Chip Driver (OCD) Impedance Calibration

The OFF-CHIP DRIVER function is an optional DDR2 JEDEC feature not supported by Micron and thereby must be set to the default state. Enabling OCD beyond the default settings will alter the I/O drive characteristics and the timing and output I/O specifications will no longer be valid (see Initialization section for proper setting of OCD defaults).

Posted CAS Additive Latency (AL)

Posted CAS additive latency (AL) is supported to make the command and data bus efficient for sustainable bandwidths in DDR2 SDRAM. Bits E3–E5 define the value of AL, as shown in Figure 35. Bits E3–E5 allow the user to program the DDR2 SDRAM with an AL of 0, 1, 2, 3, 4, 5, or 6 clocks. Reserved states should not be used as an unknown operation or incompatibility with future versions may result.

In this operation, the DDR2 SDRAM allows a READ or WRITE command to be issued prior to t_{RCD} (MIN) with the requirement that $AL \leq t_{RCD}$ (MIN). A typical application using this feature would set $AL = t_{RCD}$ (MIN) - $1 \times t_{CK}$. The READ or WRITE command is held for the time of the AL before it is issued internally to the DDR2 SDRAM device. RL is controlled by the sum of AL and CL; $RL = AL + CL$. WRITE latency (WL) is equal to RL minus one clock; $WL = AL + CL - 1 \times t_{CK}$. An example of RL is shown in Figure 36 (page 78). An example of a WL is shown in Figure 37 (page 78).

Figure 36: READ Latency

- Notes:
1. BL = 4.
 2. Shown with nominal t_{AC} , t_{DQSQ} , and t_{DQSQ} .
 3. RL = AL + CL = 5.

Figure 37: WRITE Latency

- Notes:
1. BL = 4.
 2. CL = 3.
 3. WL = AL + CL - 1 = 4.

Extended Mode Register 2 (EMR2)

The extended mode register 2 (EMR2) controls functions beyond those controlled by the mode register. Currently all bits in EMR2 are reserved, except for E7, which is used in commercial or high-temperature operations, as shown in Figure 38. The EMR2 is programmed via the LM command and will retain the stored information until it is programmed again or until the device loses power. Reprogramming the EMR will not alter the contents of the memory array, provided it is performed correctly.

Bit E7 (A7) must be programmed as 1 to provide a faster refresh rate on IT and AT devices if T_C exceeds 85°C.

EMR2 must be loaded when all banks are idle and no bursts are in progress, and the controller must wait the specified time t_{MRD} before initiating any subsequent operation. Violating either of these requirements could result in an unspecified operation.

Figure 38: EMR2 Definition

- Notes:
1. E16 (BA2) is only applicable for densities $\geq 1\text{Gb}$, reserved for future use, and must be programmed to 0.
 2. Mode bits (E_n) with corresponding address balls (A_n) greater than E12 (A12) are reserved for future use and must be programmed to 0.

Extended Mode Register 3 (EMR3)

The extended mode register 3 (EMR3) controls functions beyond those controlled by the mode register. Currently all bits in EMR3 are reserved, as shown in Figure 39. The EMR3 is programmed via the LM command and will retain the stored information until it is programmed again or until the device loses power. Reprogramming the EMR will not alter the contents of the memory array, provided it is performed correctly.

EMR3 must be loaded when all banks are idle and no bursts are in progress, and the controller must wait the specified time t_{MRD} before initiating any subsequent operation. Violating either of these requirements could result in an unspecified operation.

Figure 39: EMR3 Definition

- Notes:
1. E16 (BA2) is only applicable for densities $\geq 1\text{Gb}$, is reserved for future use, and must be programmed to 0.
 2. Mode bits (E_n) with corresponding address balls (A_n) greater than E12 (A12) are reserved for future use and must be programmed to 0.

Initialization

Figure 40: DDR2 Power-Up and Initialization

DDR2 SDRAM must be powered up and initialized in a predefined manner. Operational procedures other than those specified may result in undefined operation. Figure 40 illustrates, and the notes outline, the sequence required for power-up and initialization.

Notes: 1. Applying power; if CKE is maintained below $0.2 \times V_{DDQ}$, outputs remain disabled. To guarantee R_{TT} (ODT resistance) is off, V_{REF} must be valid and a low level must be applied to the ODT ball (all other inputs may be undefined; I/Os and outputs must be less than V_{DDQ} during voltage ramp time to avoid DDR2 SDRAM device latch-up). V_{TT} is not applied directly to the device; however, V_{TD} should be ≥ 0 to avoid device latch-up. At least one of the following two sets of conditions (A or B) must be met to obtain a stable supply state (stable supply defined as V_{DD} , V_{DDL} , V_{DDQ} , V_{REF} , and V_{TT} are between their minimum and maximum values as stated in Table 12 (page 38)):

A. Single power source: The V_{DD} voltage ramp from 300mV to $V_{DD,min}$ must take no longer than 200ms; during the V_{DD} voltage ramp, $|V_{DD} - V_{DDQ}| \leq 0.3V$. Once supply voltage ramping is complete (when V_{DDQ} crosses $V_{DD,min}$), Table 12 specifications apply.

- V_{DD} , V_{DDL} , and V_{DDQ} are driven from a single power converter output
- V_{TT} is limited to 0.95V MAX
- V_{REF} tracks $V_{DDQ}/2$; V_{REF} must be within $\pm 0.3V$ with respect to $V_{DDQ}/2$ during supply ramp time; does not need to be satisfied when ramping power down
- $V_{DDQ} \geq V_{REF}$ at all times

B. Multiple power sources: $V_{DD} \geq V_{DDL} \geq V_{DDQ}$ must be maintained during supply voltage ramping, for both AC and DC levels, until supply voltage ramping completes (V_{DDQ} crosses $V_{DD,min}$). Once supply voltage ramping is complete, Table 12 specifications apply.

- Apply V_{DD} and V_{DDL} before or at the same time as V_{DDQ} ; V_{DD}/V_{DDL} voltage ramp time must be $\leq 200ms$ from when V_{DD} ramps from 300mV to $V_{DD,min}$
- Apply V_{DDQ} before or at the same time as V_{TT} ; the V_{DDQ} voltage ramp time from when $V_{DD,min}$ is achieved to when $V_{DDQ,min}$ is achieved must be $\leq 500ms$; while V_{DD} is ramping, current can be supplied from V_{DD} through the device to V_{DDQ}
- V_{REF} must track $V_{DDQ}/2$; V_{REF} must be within $\pm 0.3V$ with respect to $V_{DDQ}/2$ during supply ramp time; $V_{DDQ} \geq V_{REF}$ must be met at all times; does not need to be satisfied when ramping power down
- Apply V_{TT} ; the V_{TT} voltage ramp time from when $V_{DDQ,min}$ is achieved to when $V_{TT,min}$ is achieved must be no greater than 500ms

2. CKE requires LVCMOS input levels prior to state T0 to ensure DQs are High-Z during device power-up prior to V_{REF} being stable. After state T0, CKE is required to have SSTL_18 input levels. Once CKE transitions to a high level, it must stay HIGH for the duration of the initialization sequence.
3. For a minimum of 200 μs after stable power and clock (CK, CK#), apply NOP or DESELECT commands, then take CKE HIGH.
4. Wait a minimum of 400ns then issue a PRECHARGE ALL command.
5. Issue a LOAD MODE command to the EMR(2). To issue an EMR(2) command, provide LOW to BA0, and provide HIGH to BA1; set register E7 to "0" or "1" to select appropriate self refresh rate; remaining EMR(2) bits must be "0" (see Extended Mode Register 2 (EMR2) (page 79) for all EMR(2) requirements).
6. Issue a LOAD MODE command to the EMR(3). To issue an EMR(3) command, provide HIGH to BA0 and BA1; remaining EMR(3) bits must be "0." Extended Mode Register 3 (EMR3) for all EMR(3) requirements.
7. Issue a LOAD MODE command to the EMR to enable DLL. To issue a DLL ENABLE command, provide LOW to BA1 and A0; provide HIGH to BA0; bits E7, E8, and E9 can be set to "0" or "1;" Micron recommends setting them to "0;" remaining EMR bits must be "0." Extended Mode Register (EMR) (page 75) for all EMR requirements.
8. Issue a LOAD MODE command to the MR for DLL RESET. 200 cycles of clock input is required to lock the DLL. To issue a DLL RESET, provide HIGH to A8 and provide LOW to BA1 and BA0; CKE must be HIGH the entire time the DLL is resetting; remaining MR bits must be "0." Mode Register (MR) (page 70) for all MR requirements.
9. Issue PRECHARGE ALL command.

10. Issue two or more REFRESH commands.
11. Issue a LOAD MODE command to the MR with LOW to A8 to initialize device operation (that is, to program operating parameters without resetting the DLL). To access the MR, set BA0 and BA1 LOW; remaining MR bits must be set to desired settings. Mode Register (MR) (page 70) for all MR requirements.
12. Issue a LOAD MODE command to the EMR to enable OCD default by setting bits E7, E8, and E9 to "1," and then setting all other desired parameters. To access the EMR, set BA0 HIGH and BA1 LOW (see Extended Mode Register (EMR) (page 75) for all EMR requirements.
13. Issue a LOAD MODE command to the EMR to enable OCD exit by setting bits E7, E8, and E9 to "0," and then setting all other desired parameters. To access the extended mode registers, EMR, set BA0 HIGH and BA1 LOW for all EMR requirements.
14. The DDR2 SDRAM is now initialized and ready for normal operation 200 clock cycles after the DLL RESET at Tf0.
15. DM represents DM for the x8 configuration and UDM, LDM for the x16 configuration; DQS represents DQS, DQS#, UDQS, UDQS#, LDQS, LDQS#, RDQS, RDQS# for the appropriate configuration (x8 or x16); DQ represents DQ[7:0] for x8 and DQ[15:0] for x16.
16. A10 = PRECHARGE ALL, CODE = desired values for mode registers (bank addresses are required to be decoded).

ACTIVATE

Before any READ or WRITE commands can be issued to a bank within the DDR2 SDRAM, a row in that bank must be opened (activated), even when additive latency is used. This is accomplished via the ACTIVATE command, which selects both the bank and the row to be activated.

After a row is opened with an ACTIVATE command, a READ or WRITE command may be issued to that row subject to the t_{RCD} specification. $t_{RCD}(\text{MIN})$ should be divided by the clock period and rounded up to the next whole number to determine the earliest clock edge after the ACTIVATE command on which a READ or WRITE command can be entered. The same procedure is used to convert other specification limits from time units to clock cycles. For example, a $t_{RCD}(\text{MIN})$ specification of 20ns with a 266 MHz clock ($t_{CK} = 3.75\text{ns}$) results in 5.3 clocks, rounded up to 6. This is shown in Figure 41, which covers any case where $5 < t_{RCD}(\text{MIN})/t_{CK} \leq 6$. Figure 41 also shows the case for t_{RRD} where $2 < t_{RRD}(\text{MIN})/t_{CK} \leq 3$.

Figure 41: Example: Meeting $t_{RRD}(\text{MIN})$ and $t_{RCD}(\text{MIN})$

A subsequent ACTIVATE command to a different row in the same bank can only be issued after the previous active row has been closed (precharged). The minimum time interval between successive ACTIVATE commands to the same bank is defined by t_{RC} .

A subsequent ACTIVATE command to another bank can be issued while the first bank is being accessed, which results in a reduction of total row-access overhead. The minimum time interval between successive ACTIVATE commands to different banks is defined by t_{RRD} .

DDR2 devices with 8 banks (1Gb or larger) have an additional requirement: t_{FAW} . This requires no more than four ACTIVATE commands may be issued in any given $t_{FAW}(\text{MIN})$ period, as shown in Figure 42 (page 85).

Figure 42: Multibank Activate Restriction

Note: 1. DDR2-533 (-37E x8), $t_{CK} = 3.75ns$, BL = 4, AL = 3, CL = 4, $t_{RRD} (MIN) = 7.5ns$, $t_{FAW} (MIN) = 37.5ns$.

READ

READ bursts are initiated with a READ command. The starting column and bank addresses are provided with the READ command, and auto precharge is either enabled or disabled for that burst access. If auto precharge is enabled, the row being accessed is automatically precharged at the completion of the burst. If auto precharge is disabled, the row will be left open after the completion of the burst.

During READ bursts, the valid data-out element from the starting column address will be available READ latency (RL) clocks later. RL is defined as the sum of AL and CL: $RL = AL + CL$. The value for AL and CL are programmable via the MR and EMR commands, respectively. Each subsequent data-out element will be valid nominally at the next positive or negative clock edge (at the next crossing of CK and CK#). Figure 43 (page 87) shows examples of RL based on different AL and CL settings.

DQS/DQS# is driven by the DDR2 SDRAM along with output data. The initial LOW state on DQS and the HIGH state on DQS# are known as the read preamble (t_{RPRE}). The LOW state on DQS and the HIGH state on DQS# coincident with the last data-out element are known as the read postamble (t_{RPST}).

Upon completion of a burst, assuming no other commands have been initiated, the DQ will go High-Z. A detailed explanation of t_{DQSQ} (valid data-out skew), t_{QH} (data-out window hold), and the valid data window are depicted in Figure 52 (page 95) and Figure 53 (page 96). A detailed explanation of t_{DQSCK} (DQS transition skew to CK) and t_{AC} (data-out transition skew to CK) is shown in Figure 54 (page 97).

Data from any READ burst may be concatenated with data from a subsequent READ command to provide a continuous flow of data. The first data element from the new burst follows the last element of a completed burst. The new READ command should be issued x cycles after the first READ command, where x equals $BL/2$ cycles (see Figure 44 (page 88)).

Nonconsecutive read data is illustrated in Figure 45 (page 89). Full-speed random read accesses within a page (or pages) can be performed. DDR2 SDRAM supports the use of concurrent auto precharge timing (see Table 41 (page 92)).

DDR2 SDRAM does not allow interrupting or truncating of any READ burst using $BL = 4$ operations. Once the $BL = 4$ READ command is registered, it must be allowed to complete the entire READ burst. However, a READ (with auto precharge disabled) using $BL = 8$ operation may be interrupted and truncated *only* by another READ burst as long as the interruption occurs on a 4-bit boundary due to the $4n$ prefetch architecture of DDR2 SDRAM. As shown in Figure 46 (page 90), READ burst $BL = 8$ operations may not be interrupted or truncated with any other command except another READ command.

Data from any READ burst must be completed before a subsequent WRITE burst is allowed. An example of a READ burst followed by a WRITE burst is shown in Figure 47 (page 90). The t_{DQSS} (NOM) case is shown (t_{DQSS} [MIN] and t_{DQSS} [MAX] are defined in Figure 55 (page 99)).

Figure 43: READ Latency

- Notes:
1. DO_n = data-out from column *n*.
 2. BL = 4.
 3. Three subsequent elements of data-out appear in the programmed order following DO_n.
 4. Shown with nominal ^tAC, ^tDQSCK, and ^tDQSQ.

Figure 44: Consecutive READ Bursts

- Notes:
1. DO *n* (or *b*) = data-out from column *n* (or column *b*).
 2. BL = 4.
 3. Three subsequent elements of data-out appear in the programmed order following DO *n*.
 4. Three subsequent elements of data-out appear in the programmed order following DO *b*.
 5. Shown with nominal t_{AC} , t_{DQSCK} , and t_{DQSQ} .
 6. Example applies only when READ commands are issued to same device.

Figure 45: Nonconsecutive READ Bursts

- Notes:
1. DO *n* (or *b*) = data-out from column *n* (or column *b*).
 2. BL = 4.
 3. Three subsequent elements of data-out appear in the programmed order following DO *n*.
 4. Three subsequent elements of data-out appear in the programmed order following DO *b*.
 5. Shown with nominal t_{AC} , t_{DQSCK} , and t_{DQSQ} .
 6. Example applies when READ commands are issued to different devices or nonconsecutive READs.

Figure 46: READ Interrupted by READ

- Notes:
1. BL = 8 required; auto precharge must be disabled (A10 = LOW).
 2. NOP or COMMAND INHIBIT commands are valid. PRECHARGE command cannot be issued to banks used for READs at T0 and T2.
 3. Interrupting READ command must be issued exactly $2 \times t_{CK}$ from previous READ.
 4. READ command can be issued to any valid bank and row address (READ command at T0 and T2 can be either same bank or different bank).
 5. Auto precharge can be either enabled (A10 = HIGH) or disabled (A10 = LOW) by the interrupting READ command.
 6. Example shown uses AL = 0; CL = 3, BL = 8, shown with nominal t_{AC} , t_{DQSCK} , and t_{DQSQ} .

Figure 47: READ-to-WRITE

- Notes:
1. BL = 4; CL = 3; AL = 2.
 2. Shown with nominal t_{AC} , t_{DQSCK} , and t_{DQSQ} .

READ with Precharge

A READ burst may be followed by a PRECHARGE command to the same bank, provided auto precharge is not activated. The minimum READ-to-PRECHARGE command spacing to the same bank has two requirements that must be satisfied: $AL + BL/2$ clocks and t_{RTP} . t_{RTP} is the minimum time from the rising clock edge that initiates the last 4-bit prefetch of a READ command to the PRECHARGE command. For BL = 4, this is the time from the actual READ (AL after the READ command) to PRECHARGE command. For BL = 8, this is the time from $AL + 2 \times CK$ after the READ-to-PRECHARGE command. Follow-

ing the PRECHARGE command, a subsequent command to the same bank cannot be issued until t_{RP} is met. However, part of the row precharge time is hidden during the access of the last data elements.

Examples of READ-to-PRECHARGE for BL = 4 are shown in Figure 48 and in Figure 49 for BL = 8. The delay from READ-to-PRECHARGE period to the same bank is $AL + BL/2 - 2CK + \text{MAX}(t_{RTP}/t_{CK} \text{ or } 2 \times CK)$ where MAX means the larger of the two.

Figure 48: READ-to-PRECHARGE – BL = 4

- Notes:
1. RL = 4 (AL = 1, CL = 3); BL = 4.
 2. $t_{RTP} \geq 2$ clocks.
 3. Shown with nominal t_{AC} , t_{DQSCK} , and t_{DQSQ} .

Figure 49: READ-to-PRECHARGE – BL = 8

- Notes:
1. RL = 4 (AL = 1, CL = 3); BL = 8.
 2. $t_{RTP} \geq 2$ clocks.
 3. Shown with nominal t_{AC} , t_{DQSCK} , and t_{DQSQ} .

READ with Auto Precharge

If A10 is high when a READ command is issued, the READ with auto precharge function is engaged. The DDR2 SDRAM starts an auto precharge operation on the rising clock edge that is $AL + (BL/2)$ cycles later than the read with auto precharge command provided $t_{RAS} (MIN)$ and t_{RTP} are satisfied. If $t_{RAS} (MIN)$ is not satisfied at this rising clock edge, the start point of the auto precharge operation will be delayed until $t_{RAS} (MIN)$ is satisfied. If $t_{RTP} (MIN)$ is not satisfied at this rising clock edge, the start point of the auto precharge operation will be delayed until $t_{RTP} (MIN)$ is satisfied. When the internal precharge is pushed out by t_{RTP} , t_{RP} starts at the point where the internal precharge happens (not at the next rising clock edge after this event).

When $BL = 4$, the minimum time from READ with auto precharge to the next ACTIVATE command is $AL + (t_{RTP} + t_{RP})/t_{CK}$. When $BL = 8$, the minimum time from READ with auto precharge to the next ACTIVATE command is $AL + 2 \text{ clocks} + (t_{RTP} + t_{RP})/t_{CK}$. The term $(t_{RTP} + t_{RP})/t_{CK}$ is always rounded up to the next integer. A general purpose equation can also be used: $AL + BL/2 - 2CK + (t_{RTP} + t_{RP})/t_{CK}$. In any event, the internal precharge does not start earlier than two clocks after the last 4-bit prefetch.

READ with auto precharge command may be applied to one bank while another bank is operational. This is referred to as concurrent auto precharge operation, as noted in Table 41. Examples of READ with precharge and READ with auto precharge with applicable timing requirements are shown in Figure 50 (page 93) and Figure 51 (page 94), respectively.

Table 41: READ Using Concurrent Auto Precharge

From Command (Bank <i>n</i>)	To Command (Bank <i>m</i>)	Minimum Delay (with Concurrent Auto Precharge)	Units
READ with auto precharge	READ or READ with auto precharge	$BL/2$	t_{CK}
	WRITE or WRITE with auto precharge	$(BL/2) + 2$	t_{CK}
	PRECHARGE or ACTIVATE	1	t_{CK}

Figure 50: Bank Read – Without Auto Precharge

- Notes:
1. NOP commands are shown for ease of illustration; other commands may be valid at these times.
 2. BL = 4 and AL = 0 in the case shown.
 3. The PRECHARGE command can only be applied at T6 if t_{RAS} (MIN) is met.
 4. READ-to-PRECHARGE = AL + BL/2 - 2CK + MAX (t_{RTP}/t_{CK} or 2CK).
 5. Disable auto precharge.
 6. "Don't Care" if A10 is HIGH at T5.
 7. I/O balls, when entering or exiting High-Z, are not referenced to a specific voltage level, but to when the device begins to drive or no longer drives, respectively.
 8. DO n = data-out from column n ; subsequent elements are applied in the programmed order.

Figure 51: Bank Read – with Auto Precharge

- Notes:
1. NOP commands are shown for ease of illustration; other commands may be valid at these times.
 2. BL = 4, RL = 4 (AL = 1, CL = 3) in the case shown.
 3. The DDR2 SDRAM internally delays auto precharge until both $t_{RAS} (MIN)$ and $t_{RTP} (MIN)$ have been satisfied.
 4. Enable auto precharge.
 5. I/O balls, when entering or exiting High-Z, are not referenced to a specific voltage level, but to when the device begins to drive or no longer drives, respectively.
 6. DO n = data-out from column n ; subsequent elements are applied in the programmed order.

Figure 52: x8 Data Output Timing – t_{DQSQ} , t_{QH} , and Data Valid Window

- Notes:
1. t_{HP} is the lesser of t_{CL} or t_{CH} clock transitions collectively when a bank is active.
 2. t_{DQSQ} is derived at each DQS clock edge, is not cumulative over time, begins with DQS transitions, and ends with the last valid transition of DQ.
 3. DQ transitioning after the DQS transition defines the t_{DQSQ} window. DQS transitions at T2 and at T2n are "early DQS," at T3 are "nominal DQS," and at T3n are "late DQS."
 4. DQ[7:0] for x8.
 5. t_{QH} is derived from t_{HP} : $t_{QH} = t_{HP} - t_{QHS}$.
 6. The data valid window is derived for each DQS transition and is defined as $t_{QH} - t_{DQSQ}$.

Figure 53: x16 Data Output Timing – t_{DQSQ} , t_{QH} , and Data Valid Window

- Notes:
1. t_{HP} is the lesser of t_{CL} or t_{CH} clock transitions collectively when a bank is active.
 2. t_{DQSQ} is derived at each DQS clock edge, is not cumulative over time, begins with DQS transitions, and ends with the last valid transition of DQ.
 3. DQ transition after the DQS transitions define the t_{DQSQ} window. LDQS defines the lower byte, and UDQS defines the upper byte.
 4. DQ0, DQ1, DQ2, DQ3, DQ4, DQ5, DQ6, or DQ7.

5. t_{QH} is derived from t_{HP} : $t_{QH} = t_{HP} - t_{QHS}$.
6. The data valid window is derived for each DQS transition and is $t_{QH} - t_{DQSQ}$.
7. DQ8, DQ9, DQ10, D11, DQ12, DQ13, DQ14, or DQ15.

Figure 54: Data Output Timing – t_{AC} and t_{DQSQ}

- Notes:
1. READ command with CL = 3, AL = 0 issued at T0.
 2. t_{DQSQ} is the DQS output window relative to CK and is the long-term component of DQS skew.
 3. DQ transitioning after DQS transitions define t_{DQSQ} window.
 4. All DQ must transition by t_{DQSQ} after DQS transitions, regardless of t_{AC} .
 5. t_{AC} is the DQ output window relative to CK and is the "long term" component of DQ skew.
 6. $t_{LZ}(\text{MIN})$ and $t_{AC}(\text{MIN})$ are the first valid signal transitions.
 7. $t_{HZ}(\text{MAX})$ and $t_{AC}(\text{MAX})$ are the latest valid signal transitions.
 8. I/O balls, when entering or exiting High-Z, are not referenced to a specific voltage level, but to when the device begins to drive or no longer drives, respectively.

WRITE

WRITE bursts are initiated with a WRITE command. DDR2 SDRAM uses WL equal to RL minus one clock cycle ($WL = RL - 1CK$) (see READ (page 69)). The starting column and bank addresses are provided with the WRITE command, and auto precharge is either enabled or disabled for that access. If auto precharge is enabled, the row being accessed is precharged at the completion of the burst.

Note: For the WRITE commands used in the following illustrations, auto precharge is disabled.

During WRITE bursts, the first valid data-in element will be registered on the first rising edge of DQS following the WRITE command, and subsequent data elements will be registered on successive edges of DQS. The LOW state on DQS between the WRITE command and the first rising edge is known as the write preamble; the LOW state on DQS following the last data-in element is known as the write postamble.

The time between the WRITE command and the first rising DQS edge is $WL \pm t_{DQSS}$. Subsequent DQS positive rising edges are timed, relative to the associated clock edge, as $\pm t_{DQSS}$. t_{DQSS} is specified with a relatively wide range (25% of one clock cycle). All of

the WRITE diagrams show the nominal case, and where the two extreme cases (t_{DQSS} [MIN] and t_{DQSS} [MAX]) might not be intuitive, they have also been included. Figure 55 (page 99) shows the nominal case and the extremes of t_{DQSS} for BL = 4. Upon completion of a burst, assuming no other commands have been initiated, the DQ will remain High-Z and any additional input data will be ignored.

Data for any WRITE burst may be concatenated with a subsequent WRITE command to provide continuous flow of input data. The first data element from the new burst is applied after the last element of a completed burst. The new WRITE command should be issued x cycles after the first WRITE command, where x equals BL/2.

Figure 56 (page 100) shows concatenated bursts of BL = 4 and how full-speed random write accesses within a page or pages can be performed. An example of nonconsecutive WRITES is shown in Figure 57 (page 100). DDR2 SDRAM supports concurrent auto precharge options, as shown in Table 42.

DDR2 SDRAM does not allow interrupting or truncating any WRITE burst using BL = 4 operation. Once the BL = 4 WRITE command is registered, it must be allowed to complete the entire WRITE burst cycle. However, a WRITE BL = 8 operation (with auto precharge disabled) might be interrupted and truncated *only* by another WRITE burst as long as the interruption occurs on a 4-bit boundary due to the $4n$ -prefetch architecture of DDR2 SDRAM. WRITE burst BL = 8 operations may *not* be interrupted or truncated with any command except another WRITE command, as shown in Figure 58 (page 101).

Data for any WRITE burst may be followed by a subsequent READ command. To follow a WRITE, t_{WTR} should be met, as shown in Figure 59 (page 102). The number of clock cycles required to meet t_{WTR} is either 2 or t_{WTR}/t_{CK} , whichever is greater. Data for any WRITE burst may be followed by a subsequent PRECHARGE command. t_{WR} must be met, as shown in Figure 60 (page 103). t_{WR} starts at the end of the data burst, regardless of the data mask condition.

Table 42: WRITE Using Concurrent Auto Precharge

From Command (Bank n)	To Command (Bank m)	Minimum Delay (with Concurrent Auto Precharge)	Units
WRITE with auto precharge	READ or READ with auto precharge	$(CL - 1) + (BL/2) + t_{WTR}$	t_{CK}
	WRITE or WRITE with auto precharge	$(BL/2)$	t_{CK}
	PRECHARGE or ACTIVATE	1	t_{CK}

Figure 55: Write Burst

- Notes:
1. Subsequent rising DQS signals must align to the clock within t_{DQSS} .
 2. $DI\ b$ = data-in for column b .
 3. Three subsequent elements of data-in are applied in the programmed order following $DI\ b$.
 4. Shown with $BL = 4$, $AL = 0$, $CL = 3$; thus, $WL = 2$.
 5. $A10$ is LOW with the WRITE command (auto precharge is disabled).

Figure 56: Consecutive WRITE-to-WRITE

- Notes:
1. Subsequent rising DQS signals must align to the clock within t_{DQSS} .
 2. DI b , etc. = data-in for column b , etc.
 3. Three subsequent elements of data-in are applied in the programmed order following DI b .
 4. Three subsequent elements of data-in are applied in the programmed order following DI n .
 5. Shown with BL = 4, AL = 0, CL = 3; thus, WL = 2.
 6. Each WRITE command may be to any bank.

Figure 57: Nonconsecutive WRITE-to-WRITE

- Notes:
1. Subsequent rising DQS signals must align to the clock within t_{DQSS} .
 2. DI b (or n), etc. = data-in for column b (or column n).
 3. Three subsequent elements of data-in are applied in the programmed order following DI b .
 4. Three subsequent elements of data-in are applied in the programmed order following DI n .
 5. Shown with BL = 4, AL = 0, CL = 3; thus, WL = 2.
 6. Each WRITE command may be to any bank.

Figure 58: WRITE Interrupted by WRITE

- Notes:
1. BL = 8 required and auto precharge must be disabled (A10 = LOW).
 2. The NOP or COMMAND INHIBIT commands are valid. The PRECHARGE command cannot be issued to banks used for WRITES at T0 and T2.
 3. The interrupting WRITE command must be issued exactly $2 \times t_{CK}$ from previous WRITE.
 4. The earliest WRITE-to-PRECHARGE timing for WRITE at T0 is $WL + BL/2 + t_{WR}$ where t_{WR} starts with T7 and not T5 (because BL = 8 from MR and not the truncated length).
 5. The WRITE command can be issued to any valid bank and row address (WRITE command at T0 and T2 can be either same bank or different bank).
 6. Auto precharge can be either enabled (A10 = HIGH) or disabled (A10 = LOW) by the interrupting WRITE command.
 7. Subsequent rising DQS signals must align to the clock within t_{DQSS} .
 8. Example shown uses AL = 0; CL = 4, BL = 8.

Figure 59: WRITE-to-READ

- Notes:
1. t_{WTR} is required for any READ following a WRITE to the same device, but it is not required between module ranks.
 2. Subsequent rising DQS signals must align to the clock within t_{DQSS} .
 3. DI b = data-in for column b ; DO n = data-out from column n .
 4. BL = 4, AL = 0, CL = 3; thus, WL = 2.
 5. One subsequent element of data-in is applied in the programmed order following DI b .
 6. t_{WTR} is referenced from the first positive CK edge after the last data-in pair.
 7. A10 is LOW with the WRITE command (auto precharge is disabled).
 8. The number of clock cycles required to meet t_{WTR} is either 2 or t_{WTR}/CK , whichever is greater.

Figure 60: WRITE-to-PRECHARGE

- Notes:
1. Subsequent rising DQS signals must align to the clock within t_{DQSS} .
 2. DI b = data-in for column b .
 3. Three subsequent elements of data-in are applied in the programmed order following DI b .
 4. BL = 4, CL = 3, AL = 0; thus, WL = 2.
 5. t_{WR} is referenced from the first positive CK edge after the last data-in pair.
 6. The PRECHARGE and WRITE commands are to the same bank. However, the PRECHARGE and WRITE commands may be to different banks, in which case t_{WR} is not required and the PRECHARGE command could be applied earlier.
 7. A10 is LOW with the WRITE command (auto precharge is disabled).

Figure 61: Bank Write – Without Auto Precharge

- Notes:
1. NOP commands are shown for ease of illustration; other commands may be valid at these times.
 2. BL = 4 and AL = 0 in the case shown.
 3. Disable auto precharge.
 4. "Don't Care" if A10 is HIGH at T9.
 5. Subsequent rising DQS signals must align to the clock within t_{DQSS} .
 6. DI n = data-in for column n ; subsequent elements are applied in the programmed order.
 7. t_{DSH} is applicable during $t_{DQSS} (MIN)$ and is referenced from CK T5 or T6.
 8. t_{DSS} is applicable during $t_{DQSS} (MAX)$ and is referenced from CK T6 or T7.

Figure 62: Bank Write – with Auto Precharge

- Notes:
1. NOP commands are shown for ease of illustration; other commands may be valid at these times.
 2. BL = 4 and AL = 0 in the case shown.
 3. Enable auto precharge.
 4. WR is programmed via MR9–MR11 and is calculated by dividing t_{WR} (in ns) by t_{CK} and rounding up to the next integer value.
 5. Subsequent rising DQS signals must align to the clock within t_{DQSS} .
 6. DI n = data-in from column n ; subsequent elements are applied in the programmed order.
 7. t_{DSH} is applicable during t_{DQSS} (MIN) and is referenced from CK T5 or T6.
 8. t_{DSS} is applicable during t_{DQSS} (MAX) and is referenced from CK T6 or T7.

Figure 63: WRITE – DM Operation

- Notes:
1. NOP commands are shown for ease of illustration; other commands may be valid at these times.
 2. BL = 4, AL = 1, and WL = 2 in the case shown.
 3. Disable auto precharge.
 4. "Don't Care" if A10 is HIGH at T11.
 5. t_{WR} starts at the end of the data burst regardless of the data mask condition.
 6. Subsequent rising DQS signals must align to the clock within t_{DQSS} .
 7. DI n = data-in for column n; subsequent elements are applied in the programmed order.
 8. t_{DSH} is applicable during $t_{DQSS} (MIN)$ and is referenced from CK T6 or T7.
 9. t_{DSS} is applicable during $t_{DQSS} (MAX)$ and is referenced from CK T7 or T8.

Figure 64: Data Input Timing

- Notes:
1. $t_{DSH}^{(MIN)}$ generally occurs during $t_{DQSS}^{(MIN)}$.
 2. $t_{DSS}^{(MIN)}$ generally occurs during $t_{DQSS}^{(MAX)}$.
 3. Subsequent rising DQS signals must align to the clock within t_{DQSS} .
 4. WRITE command issued at T0.
 5. For x16, LDQS controls the lower byte and UDQS controls the upper byte.
 6. WRITE command with WL = 2 (CL = 3, AL = 0) issued at T0.

PRECHARGE

Precharge can be initiated by either a manual PRECHARGE command or by an autoprecharge in conjunction with either a READ or WRITE command. Precharge will deactivate the open row in a particular bank or the open row in all banks. The PRECHARGE operation is shown in the previous READ and WRITE operation sections.

During a manual PRECHARGE command, the A10 input determines whether one or all banks are to be precharged. In the case where only one bank is to be precharged, bank address inputs determine the bank to be precharged. When all banks are to be precharged, the bank address inputs are treated as "Don't Care."

Once a bank has been precharged, it is in the idle state and must be activated prior to any READ or WRITE commands being issued to that bank. When a single-bank PRECHARGE command is issued, t_{RP} timing applies. When the PRECHARGE (ALL) command is issued, t_{RPA} timing applies, regardless of the number of banks opened.

REFRESH

The commercial temperature DDR2 SDRAM requires REFRESH cycles at an average interval of 7.8125 μ s (MAX) and all rows in all banks must be refreshed at least once every 64ms. The refresh period begins when the REFRESH command is registered and ends t_{RFC} (MIN) later. The average interval must be reduced to 3.9 μ s (MAX) when T_C exceeds 85°C.

Figure 65: Refresh Mode

- Notes:
1. NOP commands are shown for ease of illustration; other valid commands may be possible at these times. CKE must be active during clock positive transitions.
 2. The second REFRESH is not required and is only shown as an example of two back-to-back REFRESH commands.
 3. "Don't Care" if A10 is HIGH at this point; A10 must be HIGH if more than one bank is active (must precharge all active banks).
 4. DM, DQ, and DQS signals are all "Don't Care"/High-Z for operations shown.

SELF REFRESH

The SELF REFRESH command is initiated when CKE is LOW. The differential clock should remain stable and meet t_{CKE} specifications at least $1 \times t_{CK}$ after entering self refresh mode. The procedure for exiting self refresh requires a sequence of commands. First, the differential clock must be stable and meet t_{CK} specifications at least $1 \times t_{CK}$ prior to CKE going back to HIGH. Once CKE is HIGH ($t_{CKE} [MIN]$ has been satisfied with three clock registrations), the DDR2 SDRAM must have NOP or DESELECT commands issued for t_{XSNR} . A simple algorithm for meeting both refresh and DLL requirements is used to apply NOP or DESELECT commands for 200 clock cycles before applying any other command.

Figure 66: Self Refresh

- Notes:
1. Clock must be stable and meeting t_{CK} specifications at least $1 \times t_{CK}$ after entering self refresh mode and at least $1 \times t_{CK}$ prior to exiting self refresh mode.
 2. Self refresh exit is asynchronous; however, t_{XSNR} and t_{XSRD} timing starts at the first rising clock edge where CKE HIGH satisfies t_{ISXR} .
 3. CKE must stay HIGH until t_{XSRD} is met; however, if self refresh is being re-entered, CKE may go back LOW after t_{XSNR} is satisfied.
 4. NOP or DESELECT commands are required prior to exiting self refresh until state Tc0, which allows any nonREAD command.
 5. t_{XSNR} is required before any nonREAD command can be applied.
 6. ODT must be disabled and R_{TT} off (t_{AOFD} and t_{AOPFD} have been satisfied) prior to entering self refresh at state T1.
 7. t_{XSRD} (200 cycles of CK) is required before a READ command can be applied at state Td0.
 8. Device must be in the all banks idle state prior to entering self refresh mode.
 9. After self refresh has been entered, $t_{CKE (MIN)}$ must be satisfied prior to exiting self refresh.
 10. Upon exiting SELF REFRESH, ODT must remain LOW until t_{XSRD} is satisfied.

Power-Down Mode

DDR2 SDRAM supports multiple power-down modes that allow significant power savings over normal operating modes. CKE is used to enter and exit different power-down modes. Power-down entry and exit timings are shown in Figure 67 (page 112). Detailed power-down entry conditions are shown in Figure 68 (page 114)–Figure 75 (page 117). Table 43 (page 113) is the CKE Truth Table.

DDR2 SDRAM requires CKE to be registered HIGH (active) at all times that an access is in progress—from the issuing of a READ or WRITE command until completion of the burst. Thus, a clock suspend is not supported. For READs, a burst completion is defined when the read postamble is satisfied; for WRITEs, a burst completion is defined when the write postamble and t_{WR} (WRITE-to-PRECHARGE command) or t_{WTR} (WRITE-to-READ command) are satisfied, as shown in Figure 70 (page 115) and Figure 71 (page 115) on Figure 71 (page 115). The number of clock cycles required to meet t_{WTR} is either two or t_{WTR}/t_{CK} , whichever is greater.

Power-down mode (see Figure 67 (page 112)) is entered when CKE is registered low coincident with an NOP or DESELECT command. CKE is not allowed to go LOW during a mode register or extended mode register command time, or while a READ or WRITE operation is in progress. If power-down occurs when all banks are idle, this mode is referred to as precharge power-down. If power-down occurs when there is a row active in any bank, this mode is referred to as active power-down. Entering power-down deactivates the input and output buffers, excluding CK, CK#, ODT, and CKE. For maximum power savings, the DLL is frozen during precharge power-down. Exiting active power-down requires the device to be at the same voltage and frequency as when it entered power-down. Exiting precharge power-down requires the device to be at the same voltage as when it entered power-down; however, the clock frequency is allowed to change (see Precharge Power-Down Clock Frequency Change (page 118)).

The maximum duration for either active or precharge power-down is limited by the refresh requirements of the device t_{RFC} (MAX). The minimum duration for power-down entry and exit is limited by the t_{CKE} (MIN) parameter. The following must be maintained while in power-down mode: CKE LOW, a stable clock signal, and stable power supply signals at the inputs of the DDR2 SDRAM. All other input signals are “Don’t Care” except ODT. Detailed ODT timing diagrams for different power-down modes are shown in Figure 80 (page 123)–Figure 85 (page 127).

The power-down state is synchronously exited when CKE is registered HIGH (in conjunction with a NOP or DESELECT command), as shown in Figure 67 (page 112).

Figure 67: Power-Down

- Notes:
1. If this command is a PRECHARGE (or if the device is already in the idle state), then the power-down mode shown is precharge power-down. If this command is an ACTIVATE (or if at least one row is already active), then the power-down mode shown is active power-down.
 2. $t_{CKE (MIN)}$ of three clocks means CKE must be registered on three consecutive positive clock edges. CKE must remain at the valid input level the entire time it takes to achieve the three clocks of registration. Thus, after any CKE transition, CKE may not transition from its valid level during the time period of $t_{IS} + 2 \times t_{CK} + t_{IH}$. CKE must not transition during its t_{IS} and t_{IH} window.
 3. t_{XP} timing is used for exit precharge power-down and active power-down to any non-READ command.
 4. t_{XARD} timing is used for exit active power-down to READ command if fast exit is selected via MR (bit 12 = 0).
 5. t_{XARDS} timing is used for exit active power-down to READ command if slow exit is selected via MR (bit 12 = 1).
 6. No column accesses are allowed to be in progress at the time power-down is entered. If the DLL was not in a locked state when CKE went LOW, the DLL must be reset after exiting power-down mode for proper READ operation.

Table 43: Truth Table – CKE

Notes 1–4 apply to the entire table

Current State	CKE		Command (n) CS#, RAS#, CAS#, WE#	Action (n)	Notes
	Previous Cycle (n - 1)	Current Cycle (n)			
Power-down	L	L	X	Maintain power-down	5, 6
	L	H	DESELECT or NOP	Power-down exit	7, 8
Self refresh	L	L	X	Maintain self refresh	6
	L	H	DESELECT or NOP	Self refresh exit	7, 9, 10
Bank(s) active	H	L	DESELECT or NOP	Active power-down entry	7, 8, 11, 12
All banks idle	H	L	DESELECT or NOP	Precharge power-down entry	7, 8, 11
	H	L	Refresh	Self refresh entry	10, 12, 13
	H	H	Shown in Table 36 (page 64)		14

- Notes:
1. CKE (n) is the logic state of CKE at clock edge n; CKE (n - 1) was the state of CKE at the previous clock edge.
 2. Current state is the state of the DDR2 SDRAM immediately prior to clock edge n.
 3. Command (n) is the command registered at clock edge n, and action (n) is a result of command (n).
 4. The state of ODT does not affect the states described in this table. The ODT function is not available during self refresh (see ODT Timing (page 121) for more details and specific restrictions).
 5. Power-down modes do not perform any REFRESH operations. The duration of power-down mode is therefore limited by the refresh requirements.
 6. "X" means "Don't Care" (including floating around V_{REF}) in self refresh and power-down. However, ODT must be driven high or low in power-down if the ODT function is enabled via EMR.
 7. All states and sequences not shown are illegal or reserved unless explicitly described elsewhere in this document.
 8. Valid commands for power-down entry and exit are NOP and DESELECT only.
 9. On self refresh exit, DESELECT or NOP commands must be issued on every clock edge occurring during the t_{XSNR} period. READ commands may be issued only after t_{XSRD} (200 clocks) is satisfied.
 10. Valid commands for self refresh exit are NOP and DESELECT only.
 11. Power-down and self refresh can not be entered while READ or WRITE operations, LOAD MODE operations, or PRECHARGE operations are in progress. See SELF REFRESH (page 109) and SELF REFRESH (page 70) for a list of detailed restrictions.
 12. Minimum CKE high time is $t_{CKE} = 3 \times t_{CK}$. Minimum CKE LOW time is $t_{CKE} = 3 \times t_{CK}$. This requires a minimum of 3 clock cycles of registration.
 13. Self refresh mode can only be entered from the all banks idle state.
 14. Must be a legal command, as defined in Table 36 (page 64).

Figure 68: READ-to-Power-Down or Self Refresh Entry

- Notes: 1. In the example shown, READ burst completes at T5; earliest power-down or self refresh entry is at T6.
 2. Power-down or self refresh entry may occur after the READ burst completes.

Figure 69: READ with Auto Precharge-to-Power-Down or Self Refresh Entry

- Notes: 1. In the example shown, READ burst completes at T5; earliest power-down or self refresh entry is at T6.
 2. Power-down or self refresh entry may occur after the READ burst completes.

Figure 70: WRITE-to-Power-Down or Self Refresh Entry

Note: 1. Power-down or self refresh entry may occur after the WRITE burst completes.

Figure 71: WRITE with Auto Precharge-to-Power-Down or Self Refresh Entry

- Notes:
1. Internal PRECHARGE occurs at Ta0 when WR has completed; power-down entry may occur $1 \times t_{CK}$ later at Ta1, prior to t_{RP} being satisfied.
 2. WR is programmed through MR9–MR11 and represents $(t_{WR} \text{ [MIN]} \text{ ns} / t_{CK})$ rounded up to next integer t_{CK} .

Figure 72: REFRESH Command-to-Power-Down Entry

Note: 1. The earliest precharge power-down entry may occur is at T2, which is 1 x t_{CK} after the REFRESH command. Precharge power-down entry occurs prior to t_{RFC} (MIN) being satisfied.

Figure 73: ACTIVATE Command-to-Power-Down Entry

Note: 1. The earliest active power-down entry may occur is at T2, which is 1 x t_{CK} after the ACTIVATE command. Active power-down entry occurs prior to t_{RCD} (MIN) being satisfied.

Figure 74: PRECHARGE Command-to-Power-Down Entry

Note: 1. The earliest precharge power-down entry may occur is at T2, which is $1 \times t_{CK}$ after the PRECHARGE command. Precharge power-down entry occurs prior to $t_{RP} (MIN)$ being satisfied.

Figure 75: LOAD MODE Command-to-Power-Down Entry

- Notes:
1. Valid address for LM command includes MR, EMR, EMR(2), and EMR(3) registers.
 2. All banks must be in the precharged state and t_{RP} met prior to issuing LM command.
 3. The earliest precharge power-down entry is at T3, which is after t_{MRD} is satisfied.

Precharge Power-Down Clock Frequency Change

When the DDR2 SDRAM is in precharge power-down mode, ODT must be turned off and CKE must be at a logic LOW level. A minimum of two differential clock cycles must pass after CKE goes LOW before clock frequency may change. The device input clock frequency is allowed to change only within minimum and maximum operating frequencies specified for the particular speed grade. During input clock frequency change, ODT and CKE must be held at stable LOW levels. When the input clock frequency is changed, new stable clocks must be provided to the device before precharge power-down may be exited, and DLL must be reset via MR after precharge power-down exit. Depending on the new clock frequency, additional LM commands might be required to adjust the CL, WR, AL, and so forth. Depending on the new clock frequency, an additional LM command might be required to appropriately set the WR MR9, MR10, MR11. During the DLL relock period of 200 cycles, ODT must remain off. After the DLL lock time, the DRAM is ready to operate with a new clock frequency.

Figure 76: Input Clock Frequency Change During Precharge Power-Down Mode

- Notes:
1. A minimum of $2 \times t_{CK}$ is required after entering precharge power-down prior to changing clock frequencies.
 2. When the new clock frequency has changed and is stable, a minimum of $1 \times t_{CK}$ is required prior to exiting precharge power-down.

3. Minimum CKE high time is $t_{CKE} = 3 \times t_{CK}$. Minimum CKE LOW time is $t_{CKE} = 3 \times t_{CK}$. This requires a minimum of three clock cycles of registration.
4. If this command is a PRECHARGE (or if the device is already in the idle state), then the power-down mode shown is precharge power-down, which is required prior to the clock frequency change.

Reset

CKE Low Anytime

DDR2 SDRAM applications may go into a reset state anytime during normal operation. If an application enters a reset condition, CKE is used to ensure the DDR2 SDRAM device resumes normal operation after reinitializing. All data will be lost during a reset condition; however, the DDR2 SDRAM device will continue to operate properly if the following conditions outlined in this section are satisfied.

The reset condition defined here assumes all supply voltages (V_{DD} , V_{DDQ} , V_{DDL} , and V_{REF}) are stable and meet all DC specifications prior to, during, and after the RESET operation. All other input balls of the DDR2 SDRAM device are a “Don’t Care” during RESET with the exception of CKE.

If CKE asynchronously drops LOW during any valid operation (including a READ or WRITE burst), the memory controller must satisfy the timing parameter t_{DELAY} before turning off the clocks. Stable clocks must exist at the CK, CK# inputs of the DRAM before CKE is raised HIGH, at which time the normal initialization sequence must occur (see Initialization). The DDR2 SDRAM device is now ready for normal operation after the initialization sequence. Figure 77 (page 120) shows the proper sequence for a RESET operation.

Figure 77: RESET Function

- Notes:
1. V_{DD} , V_{DDL} , V_{DDQ} , V_{TT} , and V_{REF} must be valid at all times.
 2. Either NOP or DESELECT command may be applied.
 3. DM represents DM for x8 configuration and UDM, LDM for x16 configuration. DQS represents DQS, DQS#, UDQS, UDQS#, LDQS, LDQS#, RDQS, and RDQS# for the appropriate configuration (x8 or x16).
 4. In certain cases where a READ cycle is interrupted, CKE going HIGH may result in the completion of the burst.
 5. Initialization timing is shown in (page 0).

ODT Timing

Once a 12ns delay (t_{MOD}) has been satisfied, and after the ODT function has been enabled via the EMR LOAD MODE command, ODT can be accessed under two timing categories. ODT will operate either in synchronous mode or asynchronous mode, depending on the state of CKE. ODT can switch anytime except during self refresh mode and a few clocks after being enabled via EMR, as shown in Figure 78 (page 122).

There are two timing categories for ODT—turn-on and turn-off. During active mode (CKE HIGH) and fast-exit power-down mode (any row of any bank open, CKE LOW, MR[12 = 0]), t_{AOND} , t_{AON} , t_{AOFD} , and t_{AOF} timing parameters are applied, as shown in Figure 80 (page 123).

During slow-exit power-down mode (any row of any bank open, CKE LOW, MR[12] = 1) and precharge power-down mode (all banks/rows precharged and idle, CKE LOW), t_{AONPD} and t_{AOFPD} timing parameters are applied, as shown in Figure 81 (page 124).

ODT turn-off timing, prior to entering any power-down mode, is determined by the parameter t_{ANPD} (MIN), as shown in Figure 82 (page 124). At state T2, the ODT HIGH signal satisfies t_{ANPD} (MIN) prior to entering power-down mode at T5. When t_{ANPD} (MIN) is satisfied, t_{AOFD} and t_{AOF} timing parameters apply. Figure 82 (page 124) also shows the example where t_{ANPD} (MIN) is **not** satisfied because ODT HIGH does not occur until state T3. When t_{ANPD} (MIN) is **not** satisfied, t_{AOFPD} timing parameters apply.

ODT turn-on timing prior to entering any power-down mode is determined by the parameter t_{ANPD} , as shown in Figure 83 (page 125). At state T2, the ODT HIGH signal satisfies t_{ANPD} (MIN) prior to entering power-down mode at T5. When t_{ANPD} (MIN) is satisfied, t_{AOND} and t_{AON} timing parameters apply. Figure 83 (page 125) also shows the example where t_{ANPD} (MIN) is **not** satisfied because ODT HIGH does not occur until state T3. When t_{ANPD} (MIN) is **not** satisfied, t_{AONPD} timing parameters apply.

ODT turn-off timing after exiting any power-down mode is determined by the parameter t_{AXPD} (MIN), as shown in Figure 84 (page 126). At state Ta1, the ODT LOW signal satisfies t_{AXPD} (MIN) after exiting power-down mode at state T1. When t_{AXPD} (MIN) is satisfied, t_{AOFD} and t_{AOF} timing parameters apply. Figure 84 (page 126) also shows the example where t_{AXPD} (MIN) is **not** satisfied because ODT LOW occurs at state Ta0. When t_{AXPD} (MIN) is not satisfied, t_{AOFPD} timing parameters apply.

ODT turn-on timing after exiting either slow-exit power-down mode or precharge power-down mode is determined by the parameter t_{AXPD} (MIN), as shown in Figure 85 (page 127). At state Ta1, the ODT HIGH signal satisfies t_{AXPD} (MIN) after exiting power-down mode at state T1. When t_{AXPD} (MIN) is satisfied, t_{AOND} and t_{AON} timing parameters apply. Figure 85 (page 127) also shows the example where t_{AXPD} (MIN) is not satisfied because ODT HIGH occurs at state Ta0. When t_{AXPD} (MIN) is not satisfied, t_{AONPD} timing parameters apply.

Figure 78: ODT Timing for Entering and Exiting Power-Down Mode

MRS Command to ODT Update Delay

During normal operation, the value of the effective termination resistance can be changed with an EMRS set command. t_{MOD} (MAX) updates the R_{TT} setting.

Figure 79: Timing for MRS Command to ODT Update Delay

- Notes:
1. The LM command is directed to the mode register, which updates the information in EMR (A6, A2), that is, R_{TT} (nominal).
 2. To prevent any impedance glitch on the channel, the following conditions must be met: t_{AOFD} must be met before issuing the LM command; ODT must remain LOW for the entire duration of the t_{MOD} window until t_{MOD} is met.

This data sheet contains minimum and maximum limits specified over the power supply and temperature range set forth herein. Although considered final, these specifications are subject to change, as further product development and data characterization sometimes occur.

Компания «Life Electronics» занимается поставками электронных компонентов импортного и отечественного производства от производителей и со складов крупных дистрибьюторов Европы, Америки и Азии.

С конца 2013 года компания активно расширяет линейку поставок компонентов по направлению коаксиальный кабель, кварцевые генераторы и конденсаторы (керамические, пленочные, электролитические), за счёт заключения дистрибьюторских договоров

Мы предлагаем:

- Конкурентоспособные цены и скидки постоянным клиентам.
- Специальные условия для постоянных клиентов.
- Подбор аналогов.
- Поставку компонентов в любых объемах, удовлетворяющих вашим потребностям.
- Приемлемые сроки поставки, возможна ускоренная поставка.
- Доставку товара в любую точку России и стран СНГ.
- Комплексную поставку.
- Работу по проектам и поставку образцов.
- Формирование склада под заказчика.
- Сертификаты соответствия на поставляемую продукцию (по желанию клиента).
- Тестирование поставляемой продукции.
- Поставку компонентов, требующих военную и космическую приемку.
- Входной контроль качества.
- Наличие сертификата ISO.

В составе нашей компании организован Конструкторский отдел, призванный помогать разработчикам, и инженерам.

Конструкторский отдел помогает осуществить:

- Регистрацию проекта у производителя компонентов.
- Техническую поддержку проекта.
- Защиту от снятия компонента с производства.
- Оценку стоимости проекта по компонентам.
- Изготовление тестовой платы монтаж и пусконаладочные работы.
