

## OCTAL E1 SHORT HAUL LINE INTERFACE UNIT

IDT82V2058

### FEATURES

- ♦ Fully integrated octal E1 short haul line interface which supports 120  $\Omega$  E1 twisted pair and 75  $\Omega$  E1 coaxial applications
- ♦ Selectable Single Rail mode or Dual Rail mode and AMI or HDB3 encoder/decoder
- ♦ Built-in transmit pre-equalization meets G.703
- ♦ Selectable transmit/receive jitter attenuator meets ETSI CTR12/13, ITU G.736, G.742 and G.823 specifications
- ♦ SONET/SDH optimized jitter attenuator meets ITU G.783 mapping jitter specification
- ♦ Digital/Analog LOS detector meets ITU G.775 and ETS 300 233
- ♦ ITU G.772 non-intrusive monitoring for in-service testing for any one of channel 1 to channel 7
- ♦ Low impedance transmit drivers with high-Z
- ♦ Selectable hardware and parallel/serial host interface
- ♦ Local and Remote Loopback test functions
- ♦ Hitless Protection Switching (HPS) for 1 to 1 protection without relays
- ♦ JTAG boundary scan for board test
- ♦ 3.3 V supply with 5 V tolerant I/O
- ♦ Low power consumption
- ♦ Operating temperature range: -40°C to +85°C
- ♦ Available in 144-pin Thin Quad Flat Pack (TQFP) and 160-pin Plastic Ball Grid Array (PBGA) packages
- ♦ Green package options available

### FUNCTIONAL BLOCK DIAGRAM

Figure-1 Block Diagram

## DESCRIPTION

The IDT82V2058 is a single chip, 8-channel E1 short haul PCM transceiver with a reference clock of 2.048 MHz. The IDT82V2058 contains 8 transmitters and 8 receivers.

All the receivers and transmitters can be programmed to work either in Single Rail mode or Dual Rail mode. HDB3 or AML encoder/decoder is selectable in Single Rail mode. Pre-encoded transmit data in NRZ format can be accepted when the device is configured in Dual Rail mode. The receivers perform clock and data recovery by using integrated digital phase-locked loop. As an option, the raw sliced data (no retiming) can be output on the receive data pins. Transmit equalization is implemented with low-impedance output drivers that provide shaped waveforms to the transformer, guaranteeing template conformance.

A jitter attenuator is integrated in the IDT82V2058 and can be switched into either the transmit path or the receive path for all channels. The jitter attenuation performance meets ETSI CTR12/13, ITU G.736, G.742 and G.823 specifications.

The IDT82V2058 offers hardware control mode and software control mode. Software control mode works with either serial host interface or parallel host interface. The latter works via an Intel/Motorola compatible 8-bit parallel interface for both multiplexed or non-multiplexed applications. Hardware control mode uses multiplexed pins to select different operation modes when the host interface is not available to the device.

The IDT82V2058 also provides loopback and JTAG boundary scan testing functions. Using the integrated monitoring function, the IDT82V2058 can be configured as a 7-channel transceiver with non-intrusive protected monitoring points.

The IDT82V2058 can be used for SDH/SONET multiplexers, central office or PBX, digital access cross connects, digital radio base stations, remote wireless modules and microwave transmission systems.

## PIN CONFIGURATIONS

Data on TDn is sampled into the device on the falling edges of TCLKn, and encoded by AMI or HDB3 line code rules before being transmitted to the line.</p> <p><b>BPVIn: Bipolar Violation Insertion for Channel 0~7</b></p> <p>Bipolar violation insertion is available in Single Rail mode 2 (see Table-2 on page 13 and Table-3 on page 14) with AMI enabled. A low-to-high transition on this pin will make the next logic one to be transmitted on TDn the same polarity as the previous pulse, and violate the AMI rule. This is for testing.</p> <p><b>TDPn/TDNn: Positive/Negative Transmit Data for Channel 0~7</b></p> <p>When the device is in Dual Rail Mode, the NRZ data to be transmitted for positive/negative pulse is input on this pin. Data on TDPn/TDNn are sampled on the falling edges of TCLKn. The line code in dual rail mode is as the follow:</p> <table><tr><th>TDPn</th><th>TDNn</th><th>Output Pulse</th></tr><tr><td>0</td><td>0</td><td>Space</td></tr><tr><td>0</td><td>1</td><td>Negative Pulse</td></tr><tr><td>1</td><td>0</td><td>Positive Pulse</td></tr><tr><td>1</td><td>1</td><td>Space</td></tr></table> <p>Pulling pin TDNn high for more than 16 consecutive TCLK clock cycles will configure the corresponding channel into Single Rail mode 1 (see Table-2 on page 13 and Table-3 on page 14).</p>                                                                                                                                                                                                                                                                                                                                                                                               | TDPn | TDNn  | Output Pulse  | 0       | 0       | Space            | 0       | 1                | Negative Pulse                                                                           | 1       | 0               | Positive Pulse                                                   | 1        | 1                | Space            |                  |                            |                                                                                          |                           |                                                              |                                                                                                                                                                                              |  |          |                       |                                                            |  |

The transmit data at TDn/TDPn or TDNn is sampled into the device on the falling edges of TCLKn.</p> <p>Pulling TCLKn high for more than 16 MCLK cycles, the corresponding transmitter is set in Transmit All Ones (TAOS) state (when MCLK is clocked). In TAOS state, the TAOS generator adopts MCLK as the clock reference.</p> <p>If TCLKn is low, the corresponding transmit channel is set into power down state, while driver output ports become high-Z.</p> <p>Different combinations of TCLKn and MCLK result in different transmit mode. It is summarized as the follows:</p> <table><tr><th>MCLK</th><th>TCLKn</th><th>Transmit Mode</th></tr><tr><td>Clocked</td><td>Clocked</td><td>Normal operation</td></tr><tr><td>Clocked</td><td>High (≥ 16 MCLK)</td><td>Transmit All Ones (TAOS) signals to the line side in the corresponding transmit channel.</td></tr><tr><td>Clocked</td><td>Low (≥ 64 MCLK)</td><td>The corresponding transmit channel is set into power down state.</td></tr><tr><td rowspan="4">High/Low</td><td rowspan="4">TCLK1 is clocked</td><td>TCLKn is clocked</td><td>Normal operation</td></tr><tr><td>TCLKn is high (≥ 16 TCLK1)</td><td>Transmit All Ones (TAOS) signals to the line side in the corresponding transmit channel.</td></tr><tr><td>TCLKn is low (≥ 64 TCLK1)</td><td>Corresponding transmit channel is set into power down state.</td></tr><tr><td colspan="2">The receive path is not affected by the status of TCLK1. When MCLK is high, all receive paths just slice the incoming data stream. When MCLK is low, all the receive paths are powered down.</td></tr><tr><td>High/Low</td><td>TCLK1 is unavailable.</td><td colspan="2">All eight transmitters (TTIPn &amp; TRINGn) will be in high-Z.</td></tr></table> | MCLK | TCLKn | Transmit Mode | Clocked | Clocked | Normal operation | Clocked | High (≥ 16 MCLK) | Transmit All Ones (TAOS) signals to the line side in the corresponding transmit channel. | Clocked | Low (≥ 64 MCLK) | The corresponding transmit channel is set into power down state. | High/Low | TCLK1 is clocked | TCLKn is clocked | Normal operation | TCLKn is high (≥ 16 TCLK1) | Transmit All Ones (TAOS) signals to the line side in the corresponding transmit channel. | TCLKn is low (≥ 64 TCLK1) | Corresponding transmit channel is set into power down state. | The receive path is not affected by the status of TCLK1. When MCLK is high, all receive paths just slice the incoming data stream. When MCLK is low, all the receive paths are powered down. |  | High/Low | TCLK1 is unavailable. | All eight transmitters (TTIPn & TRINGn) will be in high-Z. |  |

|                                                                                                                                                                                                                  |                       | The receive path is not affected by the status of TCLK1. When MCLK is high, all receive paths just slice the incoming data stream. When MCLK is low, all the receive paths are powered down. |                                                                                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |      |       |               |         |         |                  |         |                  |                                                                                          |         |                 |                                                                  |          |                  |                  |                  |                            |                                                                                          |                           |                                                              |                                                                                                                                                                                              |  |          |                       |                                                            |  |

| RD0/RDP0<br>RD1/RDP1<br>RD2/RDP2<br>RD3/RDP3<br>RD4/RDP4<br>RD5/RDP5<br>RD6/RDP6<br>RD7/RDP7 | O      | 40<br>33<br>77<br>70<br>111<br>104<br>5<br>142 | P2<br>M2<br>M13<br>P13<br>A13<br>C13<br>C2<br>A2 | <p><b>RDn: Receive Data for Channel 0~7</b><br/>In Single Rail mode, the received NRZ data is output on this pin. The data is decoded by AMI or HDB3 line code rule.</p> <p><b>CVn: Code Violation for Channel 0~7</b><br/>In Single Rail mode, the bipolar violation, code violation and excessive zeros will be reported by driving pin CVn high for a full clock cycle. However, only bipolar violation is indicated when AMI decoder is selected.</p> <p><b>RDPn/RDNn: Positive/Negative Receive Data for Channel 0~7</b><br/>In Dual Rail Mode with clock recovery, these pins output the NRZ data. A high signal on RDPn indicates the receipt of a positive pulse on RTIPn/RRINGn while a high signal on RDNn indicates the receipt of a negative pulse on RTIPn/RRINGn.<br/>The output data at RDn or RDPn/RDNn are clocked out on the falling edges of RCLK when the CLKE input is low, or are clocked out on the rising edges of RCLK when CLKE is high.<br/>In Dual Rail Mode without clock recovery, these pins output the raw RZ sliced data. In this data recovery mode, the active polarity of RDPn/RDNn is determined by pin CLKE. When pin CLKE is low, RDPn/RDNn is active low. When pin CLKE is high, RDPn/RDNn is active high.<br/>In hardware mode, RDn or RDPn/RDNn will remain active during LOS. In host mode, these pins will either remain active or insert alarm indication signal (AIS) into the receive path, determined by bit AISE in register GCF.<br/>RDn or RDPn/RDNn is set into high-Z when the corresponding receiver is powered down.</p> |
| RCLK0<br>RCLK1<br>RCLK2<br>RCLK3<br>RCLK4<br>RCLK5<br>RCLK6<br>RCLK7                         | High-Z | 39<br>32<br>78<br>71<br>110<br>103<br>6<br>143 | P1<br>M1<br>M14<br>P14<br>A14<br>C14<br>C1<br>A1 | <p><b>RCLKn: Receive Clock for Channel 0~7</b><br/>In clock recovery mode, this pin outputs the recovered clock from signal received on RTIPn/RRINGn. The received data are clocked out of the device on the rising edges of RCLKn if pin CLKE is high, or on falling edges of RCLKn if pin CLKE is low.<br/>In data recovery mode, RCLKn is the output of an internal exclusive OR (XOR) which is connected with RDPn and RDNn. The clock is recovered from the signal on RCLKn.<br/>If Receiver n is powered down, the corresponding RCLKn is in high-Z.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| MCLK                                                                                         | I      | 10                                             | E1                                               | <p><b>MCLK: Master Clock</b><br/>This is an independent, free running reference clock. A clock of 2.048 MHz is supplied to this pin as the clock reference of the device for normal operation.<br/>In receive path, when MCLK is high, the device slices the incoming bipolar line signal into RZ pulse (Data Recovery mode). When MCLK is low, all the receivers are powered down, and the output pins RCLKn, RDPn and RDNn are switched to high-Z.<br/>In transmit path, the operation mode is decided by the combination of MCLK and TCLKn (see TCLKn pin description for details).<br/><b>NOTE:</b> Wait state generation via RDY/<math>\overline{\text{ACK}}</math> is not available if MCLK is not provided.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| LOS0<br>LOS1<br>LOS2<br>LOS3<br>LOS4<br>LOS5<br>LOS6<br>LOS7                                 | O      | 42<br>35<br>75<br>68<br>113<br>106<br>3<br>140 | K4<br>K3<br>K12<br>K11<br>E11<br>E12<br>E3<br>E4 | <p><b>LOSn: Loss of Signal Output for Channel 0~7</b><br/>A high level on this pin indicates the loss of signal when there is no transition over a specified period of time or no enough ones density in the received signal. The transition will return to low automatically when there is enough transitions over a specified period of time with a certain ones density in the received signal. The LOS assertion and desertion criteria are described in <a href="#">2.3.4 Loss of Signal (LOS) Detection</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

Table-1 Pin Description (Continued)

| A4<br>MC3/A3<br>MC2/A2<br>MC1/A1<br>MC0/A0                                                                   | I                                   | 12<br>13<br>14<br>15<br>16                   | F4<br>F3<br>F2<br>F1<br>G3                   | <b>MCn: Performance Monitor Configuration 3~0</b><br>In hardware control mode, A4 must be connected to GND. MC[3:0] are used to select one transmitter or receiver of channel 1 to 7 for non-intrusive monitoring. Channel 0 is used as the monitoring channel. If a transmitter is monitored, signals on the corresponding pins TTIPn and TRINGn are internally transmitted to RTIP0 and RRING0. If a receiver is monitored, signals on the corresponding pins RTIPn and RRINGn are internally transmitted to RTIP0 and RRING0. The monitored is then output to RDP0 and RDN0 pins. In host mode operation, the signals monitored by channel 0 can be routed to TTIP0/RING0 by activating the remote loopback in this channel. Refer to <a href="#">2.19 G.772 Monitoring</a> for more details.<br><br>Performance Monitor Configuration determined by MC[3:0] is shown below. Note that if MC[2:0] = 000, the device is in normal operation of all the channels. <table><tr><th>MC[3:0]</th><th>Monitoring Configuration</th></tr><tr><td>0000</td><td>Normal operation without monitoring</td></tr><tr><td>0001</td><td>Monitor Receiver 1</td></tr><tr><td>0010</td><td>Monitor Receiver 2</td></tr><tr><td>0011</td><td>Monitor Receiver 3</td></tr><tr><td>0100</td><td>Monitor Receiver 4</td></tr><tr><td>0101</td><td>Monitor Receiver 5</td></tr><tr><td>0110</td><td>Monitor Receiver 6</td></tr><tr><td>0111</td><td>Monitor Receiver 7</td></tr><tr><td>1000</td><td>Normal operation without monitoring</td></tr><tr><td>1001</td><td>Monitor Transmitter 1</td></tr><tr><td>1010</td><td>Monitor Transmitter 2</td></tr><tr><td>1011</td><td>Monitor Transmitter 3</td></tr><tr><td>1100</td><td>Monitor Transmitter 4</td></tr><tr><td>1101</td><td>Monitor Transmitter 5</td></tr><tr><td>1110</td><td>Monitor Transmitter 6</td></tr><tr><td>1111</td><td>Monitor Transmitter 7</td></tr></table><br><b>An: Address Bus 4~0</b><br>When pin MODE1 is low, the parallel host interface operates with separate address and data bus. In this mode, the signal on this pin is the address bus of the host interface. | MC[3:0] | Monitoring Configuration | 0000 | Normal operation without monitoring | 0001    | Monitor Receiver 1 | 0010 | Monitor Receiver 2 | 0011 | Monitor Receiver 3 | 0100 | Monitor Receiver 4 | 0101 | Monitor Receiver 5 | 0110 | Monitor Receiver 6 | 0111 | Monitor Receiver 7 | 1000 | Normal operation without monitoring | 1001 | Monitor Transmitter 1 | 1010 | Monitor Transmitter 2 | 1011 | Monitor Transmitter 3 | 1100 | Monitor Transmitter 4 | 1101 | Monitor Transmitter 5 | 1110 | Monitor Transmitter 6 | 1111 | Monitor Transmitter 7 |

## 2 FUNCTIONAL DESCRIPTION

### 2.1 OVERVIEW

The IDT82V2058 is a fully integrated octal short-haul line interface unit, which contains eight transmit and receive channels for use in E1 applications. The receiver performs clock and data recovery. As an option, the raw sliced data (no retiming) can be output to the system. Transmit equalization is implemented with low-impedance output drivers that provide shaped waveforms to the transformer, guaranteeing template conformance. A selectable jitter attenuator may be placed in the receive path or the transmit path. Moreover, multiple testing functions, such as error detection, loopback and JTAG boundary scan are also provided. The device is optimized for flexible software control through a serial or parallel host mode interface. Hardware control is also available. [Figure-1 on page 1](#) shows one of the eight identical channels operation.

#### 2.1.1 SYSTEM INTERFACE

The system interface of each channel can be configured to operate in different modes:

1. Single rail interface with clock recovery.
2. Dual rail interface with clock recovery.
3. Dual rail interface with data recovery (that is, with raw data slicing only and without clock recovery).

Each signal pin on system side has multiple functions depending on which operation mode the device is in.

The Dual Rail interface consists of TDPn<sup>1</sup>, TDNn, TCLKn, RDPn, RDNn and RCLKn. Data transmitted from TDPn and TDNn appears on TTIPn and TRINGn at the line interface; data received from the RTIPn and RRINGn at the line interface are transferred to RDPn and RDNn while the recovered clock extracting from the received data stream outputs on RCLKn. In Dual Rail operation, the clock/data recovery mode is selectable. Dual Rail interface with clock recovery shown in [Figure-4](#) is a default configuration mode. Dual Rail interface with data recovery is shown in [Figure-5](#). Pin RDPn and RDNn, are raw RZ slice outputs and internally connected to an EXOR which is fed to the RCLKn output for external clock recovery applications.

In Single Rail mode, data transmitted from TDn appears on TTIPn and TRINGn at the line interface. Data received from the RTIPn and RRINGn at the line interface appears on RDn while the recovered clock extracting from the received data stream outputs on RCLKn. When the device is in single rail interface, the selectable AMI or HDB3 line encoder/decoder is available and any code violation in the received data will be indicated at the CVn pin. The Single Rail mode has 2 sub-modes: Single Rail Mode 1 and Single Rail Mode 2. Single Rail Mode 1, whose interface is composed of TDn, TCLKn, RDn, CVn and RCLKn, is realized by pulling pin TDNn high for more than 16 consecutive TCLK cycles. Single Rail Mode 2, whose interface is composed of TDn, TCLKn, RDn, CVn, RCLKn and BPVIn, is realized by setting bit CRS in register **e-CRS**<sup>2</sup> and bit SING in register **e-SING**. The difference between them is that, in the latter mode bipolar violation can be inserted via pin BPVIn if AMI line code is selected.

The configuration of the Hardware Mode System Interface is summarized in [Table-2](#). The configuration of the Host Mode System Interface is summarized in [Table-3](#).

<sup>1</sup> The footprint 'n' (n = 0 - 7) indicates one of the eight channels.

<sup>2</sup> The first letter 'e-' indicates expanded register.

Note: The grey blocks are bypassed and the dotted blocks are selectable.

**Figure-4 Dual Rail Interface with Clock Recovery**

**Figure-5 Dual Rail Interface with Data Recovery****Figure-6 Single Rail Mode****Table-2 System Interface Configuration (In Hardware Mode)**

| Pin MCLK | Pin TDNn               | Interface                                                                                                                |
|----------|------------------------|--------------------------------------------------------------------------------------------------------------------------|
| Clocked  | High ( $\geq 16$ MCLK) | Single Rail Mode 1                                                                                                       |
| Clocked  | Pulse                  | Dual Rail mode with Clock Recovery                                                                                       |
| High     | Pulse                  | Dual Rail mode with Data Recovery. Receive just slices the incoming data. Transmit is determined by the status of TCLKn. |
| Low      | Pulse                  | Receiver is powered down. Transmit is determined by the status of TCLKn.                                                 |

Table-4 Active Clock Edge and Active Level

| Pin CLKE | Pin RDn/RDPn and CVn/RDNn                                                               |             |               | Pin SDO                                                                                 |             |
|----------|-----------------------------------------------------------------------------------------|-------------|---------------|-----------------------------------------------------------------------------------------|-------------|
|          | Clock Recovery                                                                          |             | Slicer Output |                                                                                         |             |
| High     | RCLKn  | Active High | Active High   | SCLK  | Active High |
| Low      | RCLKn  | Active High | Active Low    | SCLK  | Active High |

## 2.2 CLOCK EDGES

The active edge of RCLKn and SCLK are selectable. If pin CLKE is high, the active edge of RCLKn is the rising edge, as for SCLK, that is falling edge. On the contrary, if CLKE is low, the active edge of RCLK is the falling edge and that of SCLK is rising edge. Pins RDn/RDPn, CVn/RDNn and SDO are always active high, and those output signals are clocked out on the active edge of RCLKn and SCLK respectively. See [Table-4 Active Clock Edge and Active Level on page 14](#) for details. However, in dual rail mode without clock recovery, pin CLKE is used to set the active level for RDPn/RDNn raw slicing output: High for active high polarity and low for active low. It should be noted that data on pin SDI are always active high and are sampled on the rising edges of SCLK. The data on pin TDn/TDPn or BPVIn/TDNn are also always active high but are sampled on the falling edges of TCLKn, despite the level on CLKE.

## 2.3 RECEIVER

In receive path, the line signals couple into RRINGn and RTIPn via a transformer and are converted into RZ digital pulses by a data slicer. Adaptation for attenuation is achieved using an integral peak detector that sets the slicing levels. Clock and data are recovered from the received RZ digital pulses by a digital phase-locked loop that provides jitter accommodation. After passing through the selectable jitter attenuator, the recovered data are decoded using HDB3 or AMI line code rules and clocked out of pin RDn in single rail mode, or presented on RDPn/RDNn in an undecoded dual rail NRZ format. Loss of signal, alarm indication signal, line code violation and excessive zeros are detected. These various changes in status may be enabled to generate interrupts.

### 2.3.1 PEAK DETECTOR AND SLICER

The slicer determines the presence and polarity of the received pulses. In data recovery mode, the raw positive slicer output appears on RDPn while the negative slicer output appears on RDNn. In clock and

data recovery mode, the slicer output is sent to Clock and Data Recovery circuit for abstracting retimed data and optional decoding. The slicer circuit has a built-in peak detector from which the slicing threshold is derived. The slicing threshold is default to 50% (typical) of the peak value.

Signals with an attenuation of up to 12 dB (from 2.4 V) can be recovered by the receiver. To provide immunity from impulsive noise, the peak detectors are held above a minimum level of 0.150 V typically, despite the received signal level.

### 2.3.2 CLOCK AND DATA RECOVERY

The Clock and Data Recovery is accomplished by Digital Phase Locked Loop (DPLL). The DPLL is clocked 16 times of the received clock rate, i.e. 32.768 MHz in E1 mode. The recovered data and clock from DPLL is then sent to the selectable Jitter Attenuator or decoder for further processing.

The clock recovery and data recovery mode can be selected on a per channel basis by setting bit CRSn in register **e-CRS**. When bit CRSn is defaulted to '0', the corresponding channel operates in data and clock recovery mode. The recovered clock is output on pin RCLKn and re-timed NRZ data are output on pin RDPn/RDNn in dual rail mode or on RDn in single rail mode. When bit CRSn is set to '1', dual rail mode with data recovery is enabled in the corresponding channel and the clock recovery is bypassed. In this condition, the analog line signals are converted to RZ digital bit streams on the RDPn/RDNn pins and internally connected to an EXOR which is fed to the RCLKn output for external clock recovery applications.

If MCLK is pulled high, all the receivers will enter the dual rail mode with data recovery. In this case, register **e-CRS** is ignored.

### 2.3.3 HDB3/AMI LINE CODE RULE

Selectable HDB3 and AMI line coding/decoding is provided when the device is configured in single rail mode. HDB3 rules is enabled by setting bit CODE in register **GCF** to '0' or pulling pin CODE low. AMI rule is enabled by setting bit CODE in register **GCF** to '1' or pulling pin CODE high. The settings affect all eight channels.

Individual line code rule selection for each channel, if needed, is available by setting bit SINGn in register **e-SING** to '1' (to activate bit CODEn in register **e-CODE**) and programming bit CODEn to select line code rules in the corresponding channel: '0' for HDB3, while '1' for AMI. In this case, the value in bit CODE in register **GCF** or pin CODE for global control is unaffected in the corresponding channel and only affect in other channels.

In dual rail mode, the decoder/encoder are bypassed. Bit CODE in register **GCF**, bit CODEn in register **e-CODE** and pin CODE are ignored.

The configuration of the line code rule is summarized in [Table-5](#).

### 2.3.4 LOSS OF SIGNAL (LOS) DETECTION

The Loss of Signal Detector monitors the amplitude and density of the received signal on receiver line before the transformer (measured on port A, B shown in [Figure-10](#)). The loss condition is reported by pulling pin LOSn high. At the same time, LOS alarm registers track LOS condition. When LOS is detected or cleared, an interrupt will generate if not masked. In host mode, the detection supports ITU G.775 and ETSI 300 233. In hardware mode, it supports the ITU G.775.

[Table-6](#) summarizes the conditions of LOS in clock recovery mode.

During LOS, the RDPn/RDNn continue to output the sliced data when bit AISE in register **GCF** is set to '0' or output all ones as AIS (alarm indication signal) when bit AISE is set to '1'. The RCLKn is replaced by MCLK only if the bit AISE is set.

**Table-5 Configuration of the Line Code Rule**

| Hardware Mode |                      | Host Mode   |                 |                 |                      |
|---------------|----------------------|-------------|-----------------|-----------------|----------------------|
| CODE          | Line Code Rule       | CODE in GCF | CODEn in e-CODE | SINGn in e-SING | Line Code Rule       |
| Low           | All channels in HDB3 | 0           | 0/1             | 0               | All channels in HDB3 |
|               |                      | 0           | 0               | 1               |                      |
| High          | All channels in AMI  | 1           | 0/1             | 0               | All channels in AMI  |
|               |                      | 1           | 1               | 1               |                      |
|               |                      | 0           | 1               | 1               | CHn in AMI           |
|               |                      | 1           | 0               | 1               | CHn in HDB3          |

**Table-6 LOS Condition in Clock Recovery Mode**

|              |                          | Standard                                                                         |                                                                                  | Signal on LOSn |
|--------------|--------------------------|----------------------------------------------------------------------------------|----------------------------------------------------------------------------------|----------------|
|              |                          | G.775                                                                            | ETSI 300 233                                                                     |                |
| LOS Detected | Continuous Intervals     | 32                                                                               | 2048 (1 ms)                                                                      | High           |
|              | Amplitude <sup>(1)</sup> | below typical 200 mVp                                                            | below typical 200 mVp                                                            |                |
| LOS Cleared  | Density                  | 12.5% (4 marks in a sliding 32-bit period) with no more than 15 continuous zeros | 12.5% (4 marks in a sliding 32-bit period) with no more than 15 continuous zeros | Low            |
|              | Amplitude <sup>(1)</sup> | exceed typical 250 mVp                                                           | exceed typical 250 mVp                                                           |                |

<sup>1</sup> LOS levels at device (RTIPn, RRINGn) with all ones signal. For more detail regarding the LOS parameters, please refer to [Receiver Characteristics on page 42](#).

### 2.3.5 ALARM INDICATION SIGNAL (AIS) DETECTION

Alarm Indication Signal is available only in host mode with clock recovery, as shown in [Table-7](#).

### 2.3.6 ERROR DETECTION

The device can detect excessive zeros, bipolar violation and HDB3 code violation, as shown in [Figure-7](#) and [Figure-8](#). All the three kinds of errors are reported in both host mode and hardware mode with HDB3 line code rule used. In host mode, the **e-CZER** and **e-CODV** are used to

determine whether excessive zeros and code violation are reported respectively. When the device is configured in AMI decoding mode, only bipolar violation can be reported.

The error detection is available only in single rail mode in which the pin CVn/RDNn is used as error report output (CVn pin).

The configuration and report status of error detection are summarized in [Table-8](#).

**Table-7 AIS Condition**

|              | ITU G.775<br>(Register LAC defaulted to '0')                                       | ETSI 300 233<br>(Register LAC set to '1')                    |
|--------------|------------------------------------------------------------------------------------|--------------------------------------------------------------|
| AIS Detected | Less than 3 zeros contained in each of two consecutive 512-bit stream are received | Less than 3 zeros contained in a 512-bit stream are received |
| AIS Cleared  | 3 or more zeros contained in each of two consecutive 512-bit stream are received   | 3 or more zeros contained in a 512-bit stream are received   |

Table-8 Error Detection

| Hardware Mode |                                                            |
|---------------|------------------------------------------------------------|
| Line Code     | Pin CVn Reports                                            |

|           | 1               | 0               | Bipolar Violation                                    |
|           | 1               | 1               | Bipolar Violation + Excessive Zeros                  |

Figure-7 AMI Bipolar Violation

Figure-8 HDB3 Code Violation &amp; Excessive Zeros

## 2.4 TRANSMITTER

In transmit path, data in NRZ format are clocked into the device on TDn and encoded by AMI or HDB3 line code rules when single rail mode is configured or pre-encoded data in NRZ format are input on TDPn and TDNn when dual rail mode is configured. The data are sampled into the device on falling edges of TCLKn. Jitter attenuator, if enabled, is

provided with a FIFO through which the data to be transmitted are passing. A low jitter clock is generated by an integral digital phase-locked loop and is used to read data from the FIFO. The shape of the pulses should meet the E1 pulse template after the signal passes through different cable lengths or types. Bipolar violation, for diagnosis, can be inserted on pin BPVn if AMI line code rule is enabled.

### 2.4.1 WAVEFORM SHAPER

E1 pulse template, specified in ITU-T G.703, is shown in [Figure-9](#). The device has built-in transmit waveform templates for cable of 75  $\Omega$  or 120  $\Omega$ .

The built-in waveform shaper uses an internal high frequency clock which is 16XMCLK as the clock reference. This function will be bypassed when MCLK is unavailable.

**Figure-9 CEPT Waveform Template**

### 2.4.2 BIPOLAR VIOLATION INSERTION

When configured in Single Rail Mode 2 with AMI line code enabled, pin TDNn/BPVIn is used as BPVI input. A low-to-high transition on this pin inserts a bipolar violation on the next available mark in the transmit data stream. Sampling occurs on the falling edges of TCLK. But in TAOS (Transmit All Ones) with Analog Loopback and Remote Loopback, the BPVI is disabled. In TAOS with Digital Loopback, the BPVI is looped back to the system side, so the data to be transmitted on TTIPn and TRINGn are all ones with no bipolar violation.

## 2.5 JITTER ATTENUATOR

The jitter attenuator can be selected to work either in transmit path or in receive path or not used. The selection is accomplished by setting pin JAS in hardware mode or configuring bits JACF[1:0] in register **GCF** in host mode, which affects all eight channels.

For applications which require line synchronization, the line clock needed to be extracted for the internal synchronization, the jitter attenuator is set in the receive path. Another use of the jitter attenuator is to provide clock smoothing in the transmit path for applications such as synchronous/asynchronous demultiplexing applications. In these applications, TCLK will have an instantaneous frequency that is higher than the nominal E1 data rate and in order to set the average long-term TCLK frequency within the transmit line rate specifications, periods of TCLK are suppressed (gapped).

The jitter attenuator integrates a FIFO which can accommodate a gapped TCLK. In host mode, the FIFO length can be 32 X 2 or 64 X 2 bits by programming bit JADP in **GCF**. In hardware mode, it is fixed to 64 X 2 bits. The FIFO length determines the maximum permissible gap width (see [Table-9 Gap Width Limitation](#)). Exceeding these values will cause FIFO overflow or underflow. The data is 16 or 32 bits' delay through the jitter attenuator in the corresponding transmit or receive path. The constant delay feature is crucial for the applications requiring "hitless" switching.

**Table-9 Gap Width Limitation**

| FIFO Length | Max. Gap Width |
|-------------|----------------|
| 64 bit      | 56 UI          |
| 32 bit      | 28 UI          |

In host mode, bit JABW in GCF determines the jitter attenuator 3 dB corner frequency (fc). In hardware mode, the fc is fixed to 1.7 Hz. Generally, the lower the fc is, the higher the attenuation. However, lower fc comes at the expense of increased acquisition time. Therefore, the optimum fc is to optimize both the attenuation and the acquisition time. In addition, the longer FIFO length results in an increased throughput delay and also influences the 3 dB corner frequency. Generally, it's recommended to use the lower corner frequency and the shortest FIFO length that can still meet jitter attenuation requirements.

The output jitter meets ITU-T G.736, ITU-T G.742, ITU-T G.783 and ETSI CTR 12/13.

## 2.6 LINE INTERFACE CIRCUITRY

The transmit and receive interface RTIPn/RRINGn and TTIPn/TRINGn connections provide a matched interface to the cable. [Figure-10](#) shows the appropriate external components to connect with the cable for one transmit/receive channel. [Table-10](#) summarizes the component values based on the specific application.

Table-10 External Components Values

| Component | 75 $\Omega$ Coax                                                                              | 120 $\Omega$ Twisted Pair |
|-----------|-----------------------------------------------------------------------------------------------|---------------------------|
| $R_T$     | $9.5 \Omega \pm 1\%$                                                                          | $9.5 \Omega \pm 1\%$      |
| $R_R$     | $9.31 \Omega \pm 1\%$                                                                         | $15 \Omega \pm 1\%$       |
| $C_p$     | 2200 pF                                                                                       |                           |
| D1 - D4   | Nihon Inter Electronics - EP05Q03L, 11EQS03L,<br>EC10QS04, EC10QS03L;<br>Motorola - MBR0540T1 |                           |

NOTE:

1. Pulse T1124 transformer is recommended to be used in Standard (STD) operating temperature range (0°C to 70°C), while Pulse T1114 transformer is recommended to be used in Extended (EXT) operating temperature range is -40°C to +85°C. See Transformer Specifications Table for details.
2. Typical value. Adjust for actual board parasitics to obtain optimum return loss.
3. Common decoupling capacitor for all VDDT and GNDT pins. One per chip.

Figure-10 External Transmit/Receive Line Circuitry

## 2.7 TRANSMIT DRIVER POWER SUPPLY

All transmit driver power supplies must be 5.0 V or 3.3 V.

Despite the power supply voltage, the 75  $\Omega$ /120  $\Omega$  lines are driven through a pair of 9.5  $\Omega$  series resistors and a 1:2 transformer.

Table-11 Transformer Specifications<sup>(1)</sup>

| Electrical Specification @ 25°C |           |                             |         |                     |         |                         |         |                           |         |                   |
|---------------------------------|-----------|-----------------------------|---------|---------------------|---------|-------------------------|---------|---------------------------|---------|-------------------|
| Part No.                        |           | Turns Ratio (Pri: sec ± 2%) |         | OCL @ 25°C (mH MIN) |         | L <sub>L</sub> (μH MAX) |         | C <sub>W/W</sub> (pF MAX) |         | Package/Schematic |
| STD Temp.                       | EXT Temp. | Transmit                    | Receive | Transmit            | Receive | Transmit                | Receive | Transmit                  | Receive |                   |
| T1124                           | T1114     | 1:2CT                       | 1CT:2   | 1.2                 | 1.2     | .6                      | .6      | 35                        | 35      |                   |

<sup>(1)</sup> Pulse T1124 transformer is recommended to be used in Standard (STD) operating temperature range (0°C to 70°C), while Pulse T1114 transformer is recommended to be used in Extended (EXT) operating temperature range is -40°C to +85°C.

## 2.8 POWER DRIVER FAILURE MONITOR

An internal power Driver Failure Monitor (DFMON), parallel connected with TTIPn and TRINGn, can detect short circuit failure between TTIPn and TRINGn pins. Bit SCPB in register **GCF** decides whether the output driver short circuit protection is enabled. When the short circuit protection is enabled, the driver output current is limited to a typical value: 180 mAp. Also, register **DF**, **DFI** and **DFM** will be available. When DFMON will detect a short circuit, register **DF** will be set. With a short circuit failure detected and short circuit protection enabled, register **DFI** will be set and an interrupt will be generated on pin  $\overline{INT}$ .

## 2.9 TRANSMIT LINE SIDE SHORT CIRCUIT FAILURE DETECTION

A pair of 9.5  $\Omega$  serial resistors connect with TTIPn and TRINGn pins and limit the output current. In this case, the output current is a limited value which is always lower than the typical line short circuit current 180 mAp, even if the transmit line side is shorted.

Refer to [Table-10 External Components Values](#) for details.

## 2.10 LINE PROTECTION

In transmit side, the Schottky diodes D1~D4 are required to protect the line driver and improve the design robustness. In receive side, the series resistors of 1 k $\Omega$  are used to protect the receiver against current surges coupled in the device. The series resistors do not affect the receiver sensitivity, since the receiver impedance is as high as 120 k $\Omega$  typically.

## 2.11 HITLESS PROTECTION SWITCHING (HPS)

The IDT82V2058 transceivers include an output driver with high-Z feature for E1 redundancy applications. This feature reduces the cost of redundancy protection by eliminating external relays. Details of HPS are described in relative Application Note.

## 2.12 SOFTWARE RESET

Writing register **RS** will cause software reset by initiating about 1  $\mu$ s reset cycle. This operation set all the registers to their default value.

## 2.13 POWER ON RESET

During power up, an internal reset signal sets all the registers to default values. The power-on reset takes at least 10  $\mu$ s, starting from when the power supply exceeds 2/3 VDDA.

## 2.14 POWER DOWN

Each transmit channel will be powered down by pulling pin TCLKn low for more than 64 MCLK cycles (if MCLK is available) or about 30  $\mu$ s (if MCLK is not available). In host mode, each transmit channel will also be powered down by setting bit TPDn in register **e-TPDN** to '1'.

All the receivers will be powered down when MCLK is low. When MCLK is clocked or high, setting bit RPDn in register **e-RPDN** to '1' will configure the corresponding receiver to be powered down.

## 2.15 INTERFACE WITH 5 V LOGIC

The IDT82V2058 can interface directly with 5 V TTL family devices. The internal input pads are tolerant to 5 V output from TTL and CMOS family devices.

## 2.16 LOOPBACK MODE

The device provides four different diagnostic loopback configurations: Digital Loopback, Analog Loopback, Remote Loopback and Dual Loopback. In host mode, these functions are implemented by programming the registers **DLB**, **ALB** and **RLB** respectively. In hardware mode, only Analog Loopback and Remote Loopback can be selected by pin LPn.

### 2.16.1 DIGITAL LOOPBACK

By programming the bits of register **DLB**, each channel of the device can be configured in Local Digital Loopback. In this configuration, the data and clock to be transmitted, after passing the encoder, are looped back to Jitter Attenuator (if enabled) and decoder in the receive path, then output on RCLKn, RDn/RDPn and CVn/RDNn. The data to be transmitted are still output on TTIPn and TRINGn while the data received on RTIPn and RRINGn are ignored. The Loss Detector is still in use. [Figure-11](#) shows the process.

During Digital Loopback, the received signal on the receive line is still monitored by the LOS Detector (See [2.3.4 Loss of Signal \(LOS\) Detection](#) for details). In case of a LOS condition and AIS insertion enabled, all ones signal will be output on RDPn/RDNn. With ATAO enabled, all ones signal will be also output on TTIPn/TRINGn. AIS insertion can be enabled by setting AISE bit in register **GCF** and ATAO can be enabled by setting register **ATAO** (default disabled).

### 2.16.2 ANALOG LOOPBACK

By programming the bits of register **ALB** or pulling pin LPn high, each channel of the device can be configured in Analog Loopback. In this configuration, the data to be transmitted output from the line driver are internally looped back to the slicer and peak detector in the receive path and output on RCLKn, RDn/RDPn and CVn/RDNn. The data to be transmitted are still output on TTIPn and TRINGn while the data received on RTIPn and RRINGn are ignored. The LOS Detector (See [2.3.4 Loss of Signal \(LOS\) Detection](#) for details) is still in use and monitors the internal looped back data. If a LOS condition on TDPn/TDNn is expected during Analog Loopback, ATAO should be disabled (default). [Figure-12](#) shows the process.

The TTIPn and RTIPn, TRINGn and RRINGn cannot be connected directly to do the external analog loopback test. Line impedance loading is required to conduct the external analog loopback test.

### 2.16.3 REMOTE LOOPBACK

By programming the bits of register **RLB** or pulling pin LPn low, each channel of the device can be set in Remote Loopback. In this configuration, the data and clock recovered by the clock and data recovery circuits are looped to waveform shaper and output on TTIPn and TRINGn. The jitter attenuator is also included in loopback when enabled in the transmit or receive path. The received data and clock are still output on RCLKn, RDn/RDPn and CVn/RDNn while the data to be transmitted on TCLKn, TDn/TDPn and BPVn/TDNn are ignored. The LOS Detector is still in use. [Figure-13](#) shows the process.

### 2.16.4 DUAL LOOPBACK

Dual Loopback mode is set by setting bit DLBn in register **DLB** and bit RLBn in register **RLB** to '1'. In this configuration, after passing the encoder, the data and clock to be transmitted are looped back to decoder directly and output on RCLKn, RDn/RDPn and CVn/RDNn. The recovered data from RTIPn and RRINGn are looped back to waveform shaper through JA (if selected) and output on TTIPn and TRINGn. The LOS Detector is still in use. [Figure-14](#) shows the process.

### 2.16.5 TRANSMIT ALL ONES (TAOS)

In hardware mode, the TAOS mode is set by pulling pin TCLKn high for more than 16 MCLK cycles. In host mode, TAOS mode is set by programming register **TAO**. In addition, automatic TAOS signals are inserted by setting register **ATAO** when Loss of Signal occurs. Note that the TAOS generator adopts MCLK as a timing reference. In order to assure that the output frequency is within specified limits, MCLK must have the applicable stability.

The TAOS mode, the TAOS mode with Digital Loopback and the TAOS mode with Analog Loopback are shown in [Figure-15](#), [Figure-16](#) and [Figure-17](#).

**Figure-11 Digital Loopback****Figure-12 Analog Loopback****Figure-13 Remote Loopback**

## 2.17 HOST INTERFACE

The host interface provides access to read and write the registers in the device. The interface consists of serial host interface and parallel host interface. By pulling pin MODE2 to VDDIO/2 or high, the device can be set to work in serial mode and in parallel mode respectively.

### 2.17.1 PARALLEL HOST INTERFACE

The interface is compatible with Motorola and Intel host. Pins MODE1 and MODE0 are used to select the operating mode of the parallel host interface. When pin MODE1 is pulled low, the host uses separate address bus and data bus. When high, multiplexed address/data bus is used. When pin MODE0 is pulled low, the parallel host interface is configured for Motorola compatible hosts. When pin MODE0 is pulled high, the parallel host interface is configured for Intel compatible hosts. See [Table-1 Pin Description](#) for more details. The host interface pins in each operation mode is tabulated in [Table-12](#):

Table-12 Parallel Host Interface Pins

| MODE[2:0] | Host Interface                     | Generic Control, Data and Output Pin                                                                                         |
|-----------|------------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| 100       | Non-multiplexed Motorola interface | $\overline{CS}$ , $\overline{ACK}$ , $\overline{DS}$ , $\overline{R/W}$ , $\overline{AS}$ , A[4:0], D[7:0], $\overline{INT}$ |
| 101       | Non-multiplexed Intel interface    | $\overline{CS}$ , RDY, WR, $\overline{RD}$ , ALE, A[4:0], D[7:0], $\overline{INT}$                                           |
| 110       | Multiplexed Motorola interface     | $\overline{CS}$ , $\overline{ACK}$ , $\overline{DS}$ , $\overline{R/W}$ , $\overline{AS}$ , AD[7:0], $\overline{INT}$        |
| 111       | Multiplexed Intel interface        | $\overline{CS}$ , RDY, WR, $\overline{RD}$ , ALE, AD[7:0], $\overline{INT}$                                                  |

Figure-18 Serial Host Mode Timing

### 2.17.2 SERIAL HOST INTERFACE

By pulling pin MODE2 to VDDIO/2, the device operates in the serial host Mode. In this mode, the registers are accessible through a 16-bit word which contains an 8-bit command/address byte (bit R/W and 5-address-bit A1~A5, A6 and A7 bits are ignored) and a subsequent 8-bit

data byte (D7~D0), as shown in [Figure-18](#). When bit  $\overline{R/W}$  is set to '1', data is read out from pin SDO. When bit  $\overline{R/W}$  is set to '0', data on pin SDI is written into the register whose address is indicated by address bits A5~A1. See [Figure-18 Serial Host Mode Timing](#).

## 2.18 INTERRUPT HANDLING

### 2.18.1 INTERRUPT SOURCES

There are three kinds of interrupt sources:

1. *Status change in register **LOS**. The analog/digital loss of signal detector continuously monitors the received signal to update the specific bit in register **LOS** which indicates presence or absence of a LOS condition.*
2. *Status change in register **DF**. The automatic power driver circuit continuously monitors the output drivers signal to update the specific bit in register **DFM** which indicates presence or absence of an output driver short circuit condition.*
3. *Status change in register **AIS**. The AIS detector monitors the received signal to update the specific bit in register **AIS** which indicates presence or absence of a AIS condition.*

**Figure-19 Interrupt Service Routine**

### 2.18.2 INTERRUPT ENABLE

The IDT82V2058 provides a latched interrupt output ( $\overline{\text{INT}}$ ) and the four kinds of interrupts are all reported by this pin. When the Interrupt Mask register (**LOSM**, **DFM** and **AISM**) is set to '1', the Interrupt Status register (**LOSI**, **DFI** and **AISI**) is enabled respectively. Whenever there is a transition ('0' to '1' or '1' to '0') in the corresponding status register, the Interrupt Status register will change into '1', which means an interrupt occurs, and there will be a high to low transition on  $\overline{\text{INT}}$  pin. An external pull-up resistor of approximately 10 k $\Omega$  is required to support the wire-OR operation of  $\overline{\text{INT}}$ . When any of the three Interrupt Mask registers is set to '0' (the power-on default value is '0'), the corresponding Interrupt Status register is disabled and the transition on status register is ignored.

### 2.18.3 INTERRUPT CLEARING

When an interrupt occurs, the Interrupt Status registers: **LOSI**, **DFI** and **AISI**, are read to identify the interrupt source. These registers will be cleared to '0' after the corresponding status registers: **LOS**, **DF** and **AIS** are read. The Status registers will be cleared once the corresponding conditions are met.

Pin  $\overline{\text{INT}}$  is pulled high when there is no pending interrupt left. The interrupt handling in the interrupt service routine is showed in [Figure-19](#).

## 2.19 G.772 MONITORING

The eight channels of IDT82V2058 can all be configured to work as regular transceivers. In applications using only seven channels (channels 1 to 7), channel 0 is configured to non-intrusively monitor any of the other channels' inputs or outputs on the line side. The monitoring is non-intrusive per ITU-T G.772. [Figure-20](#) shows the Monitoring Principle. The receiver path or transmitter path to be monitored is configured by pins MC[3:0] in hardware mode or by register **PMON** in host mode.

The monitored signal goes through the clock and data recovery circuit of channel 0. The monitored clock can output on RCLK0 which can be used as a timing interfaces derived from E1 signal. The monitored data can be observed digitally at the output pins RCLK0, RD0/RDP0 and RDN0. LOS detector is still in use in channel 0 for the monitored signal.

In monitoring mode, channel 0 can be configured in Remote Loop-back. The signal which is being monitored will output on TTIP0 and TRING0. The output signal can then be connected to a standard test equipment with an E1 electrical interface for non-intrusive monitoring.

Figure-20 Monitoring Principle

### 3 PROGRAMMING INFORMATION

#### 3.1 REGISTER LIST AND MAP

There are 21 primary registers (including an Address Pointer Control Register and 8 expanded registers in the device).

Whatever the control interface is, 5 address bits are used to set the registers. In non-multiplexed parallel interface mode, the five dedicated address bits are A[4:0]. In multiplexed parallel interface mode, AD[4:0] carries the address information. In serial interface mode, A[5:1] are used to address the register.

The Register **ADDP**, addressed as 11111 or 1F Hex, switches between primary registers bank and expanded registers bank.

By setting the register **ADDP** to 'AAH', the 5 address bits point to the expanded register bank, that is, the expanded registers are available. By clearing register **ADDP**, the primary registers are available.

Primary Registers, whose addresses are 10H, 11H, 16H to 1EH, are reserved. Expanded registers, whose addresses are 08H to 1EH, are used for test and must be set to '0' (default).

Table-13 Primary Register List

| Address |                        |                          | Register | R/W | Explanation                                                                                             |

## 3.2 REGISTER DESCRIPTION

### 3.2.1 PRIMARY REGISTERS

**ID:** Device ID Register (R, Address = 00H)

| Symbol  | Position | Default | Description                                                                                                                                                      |
|---------|----------|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ID[7:0] | ID.7-0   | 10H     | An 8-bit word is pre-set into the device as the identification and revision number. This number is different with the functional changes and is mask programmed. |

**ALB:** Analog Loopback Configuration Register (R/W, Address = 01H)

| Symbol   | Position | Default | Description                                                     |
|----------|----------|---------|-----------------------------------------------------------------|
| ALB[7:0] | ALB.7-0  | 00H     | 0 = Normal operation. (Default)<br>1 = Analog Loopback enabled. |

**RLB:** Remote Loopback Configuration Register (R/W, Address = 02H)

| Symbol   | Position | Default | Description                                                     |
|----------|----------|---------|-----------------------------------------------------------------|
| RLB[7:0] | RLB.7-0  | 00H     | 0 = Normal operation. (Default)<br>1 = Remote Loopback enabled. |

**TAO:** Transmit All Ones Configuration Register (R/W, Address = 03H)

| Symbol   | Position | Default | Description                                               |
|----------|----------|---------|-----------------------------------------------------------|
| TAO[7:0] | TAO.7-0  | 00H     | 0 = Normal operation. (Default)<br>1 = Transmit all ones. |

**LOS:** Loss of Signal Status Register (R, Address = 04H)

| Symbol   | Position | Default | Description                                                     |
|----------|----------|---------|-----------------------------------------------------------------|
| LOS[7:0] | LOS.7-0  | 00H     | 0 = Normal operation. (Default)<br>1 = Loss of signal detected. |

**DF:** Driver Fault Status Register (R, Address = 05H)

| Symbol  | Position | Default | Description                                                   |
|---------|----------|---------|---------------------------------------------------------------|
| DF[7:0] | DF.7-0   | 00H     | 0 = Normal operation. (Default)<br>1 = Driver fault detected. |

**LOSM:** Loss of Signal Interrupt Mask Register (R/W, Address = 06H)

| Symbol    | Position | Default | Description                                                                  |
|-----------|----------|---------|------------------------------------------------------------------------------|
| LOSM[7:0] | LOSM.7-0 | 00H     | 0 = LOS interrupt is not allowed. (Default)<br>1 = LOS interrupt is allowed. |

**DFM:** Driver Fault Interrupt Mask Register (R/W, Address = 07H)

| Symbol   | Position | Default | Description                                                                              |
|----------|----------|---------|------------------------------------------------------------------------------------------|
| DFM[7:0] | DFM.7-0  | 00H     | 0 = Driver fault interrupt not allowed. (Default)<br>1 = Driver fault interrupt allowed. |

**LOSI:** Loss of Signal Interrupt Status Register (R, Address = 08H)

| Symbol    | Position | Default | Description                                                                                                                                                 |
|-----------|----------|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LOSI[7:0] | LOSI.7-0 | 00H     | 0 = (Default). Or after a <b>LOS</b> read operation.<br>1 = Any transition on <b>LOS<sub>n</sub></b> (Corresponding <b>LOSM<sub>n</sub></b> is set to '1'). |

**DFI:** Driver Fault Interrupt Status Register (R, Address = 09H)

| Symbol   | Position | Default | Description                                                                                                                        |
|----------|----------|---------|------------------------------------------------------------------------------------------------------------------------------------|
| DFI[7:0] | DFI.7-0  | 00H     | 0 = (Default). Or after a <b>DF</b> read operation.<br>1 = Any transition on <b>DFn</b> (Corresponding <b>DFMn</b> is set to '1'). |

**RS:** Software Reset Register (W, Address = 0AH)

| Symbol  | Position | Default | Description                                                                                                                                                                              |
|---------|----------|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RS[7:0] | RS.7-0   | FFH     | Writing to this register will not change the content in this register but initiate a 1 $\mu$ s reset cycle, which means all the registers in the device are set to their default values. |

**PMON:** Performance Monitor Configuration Register (R/W, Address = 0BH)

| Symbol  | Position | Default | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------|----------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -       | PMON.7-4 | 0000    | 0 = Normal operation. (Default)<br>1 = Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| MC[3:0] | PMON.3-0 | 0000    | 0000 = Normal operation without monitoring (Default)<br>0001 = Monitor Receiver 1<br>0010 = Monitor Receiver 2<br>0011 = Monitor Receiver 3<br>0100 = Monitor Receiver 4<br>0101 = Monitor Receiver 5<br>0110 = Monitor Receiver 6<br>0111 = Monitor Receiver 7<br>1000 = Normal operation without monitoring<br>1001 = Monitor Transmitter 1<br>1010 = Monitor Transmitter 2<br>1011 = Monitor Transmitter 3<br>1100 = Monitor Transmitter 4<br>1101 = Monitor Transmitter 5<br>1110 = Monitor Transmitter 6<br>1111 = Monitor Transmitter 7 |

**DLB:** Digital Loopback Configuration Register (R/W, Address = 0CH)

| Symbol   | Position | Default | Description                                                      |
|----------|----------|---------|------------------------------------------------------------------|
| DLB[7:0] | DLB.7-0  | 00H     | 0 = Normal operation. (Default)<br>1 = Digital Loopback enabled. |

**LAC:** LOS/AIS Criteria Configuration Register (R/W, Address = 0DH)

| Symbol   | Position | Default | Description                             |
|----------|----------|---------|-----------------------------------------|
| LAC[7:0] | LAC.7-0  | 00H     | 0 = G.775 (Default)<br>1 = ETSI 300 233 |

**ATAO:** Automatic TAOS Configuration Register (R/W, Address = 0EH)

| Symbol    | Position | Default | Description                                                                                                   |
|-----------|----------|---------|---------------------------------------------------------------------------------------------------------------|
| ATAO[7:0] | ATAO.7-0 | 00H     | 0 = No automatic transmit all ones. (Default)<br>1 = Automatic transmit all ones to the line side during LOS. |

**GCF:** Global Configuration Register (R/W, Address = 0FH)

| Symbol    | Position | Default | Description                                                                                                                                |
|-----------|----------|---------|--------------------------------------------------------------------------------------------------------------------------------------------|
| -         | GCF.7    | 0       | 0 = Normal operation.<br>1 = Reserved.                                                                                                     |
| AISE      | GCF.6    | 0       | 0 = AIS insertion to the system side disabled on LOS.<br>1 = AIS insertion to the system side enabled on LOS.                              |
| SCPB      | GCF.5    | 0       | 0 = Short circuit protection is enabled.<br>1 = Short circuit protection is disabled.                                                      |
| CODE      | GCF.4    | 0       | 0 = HDB3 encoder/decoder enabled.<br>1 = AMI encoder/decoder enabled.                                                                      |
| JADP      | GCF.3    | 0       | Jitter Attenuator Depth Select<br>0 = 32-bit FIFO (Default)<br>1 = 64-bit FIFO                                                             |
| JABW      | GCF.2    | 0       | Jitter Transfer Function Bandwidth Select<br>0 = 1.7 Hz<br>1 = 6.6 Hz                                                                      |
| JACF[1:0] | GCF.1-0  | 00      | Jitter Attenuator Configuration<br>00 = JA not used. (Default)<br>01 = JA in transmit path<br>10 = JA not used.<br>11 = JA in receive path |

**OE:** Output Enable Configuration Register (R/W, Address = 12H)

| Symbol  | Position | Default | Description                                                                |
|---------|----------|---------|----------------------------------------------------------------------------|
| OE[7:0] | OE.7-0   | 00H     | 0 = Transmit drivers enabled. (Default)<br>1 = Transmit drivers in high-Z. |

**AIS:** Alarm Indication Signal Status Register (R, Address = 13H)

| Symbol   | Position | Default | Description                                          |
|----------|----------|---------|------------------------------------------------------|
| AIS[7:0] | AIS.7-0  | 00H     | 0 = Normal operation. (Default)<br>1 = AIS detected. |

**AISM:** Alarm Indication Signal Interrupt Mask Register (R/W, Address = 14H)

| Symbol    | Position | Default | Description                                                                  |
|-----------|----------|---------|------------------------------------------------------------------------------|
| AISM[7:0] | AISM.7-0 | 00H     | 0 = AIS interrupt is not allowed. (Default)<br>1 = AIS interrupt is allowed. |

**AISI:** Alarm Indication Signal Interrupt Status Register (R, Address = 15H)

| Symbol    | Position | Default | Description                                                                                                                             |
|-----------|----------|---------|-----------------------------------------------------------------------------------------------------------------------------------------|
| AISI[7:0] | AISI.7-0 | 00H     | 0 = (Default), or after an <b>AIS</b> read operation<br>1 = Any transition on <b>AISn</b> . (Corresponding <b>AISMn</b> is set to '1'.) |

**ADDP:** Address Pointer Control Register (R/W, Address = 1F H)

| Symbol    | Position | Default | Description                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------|----------|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ADDP[7:0] | ADDP.7-0 | 00H     | Two kinds of configuration in this register can be set to switch between primary register bank and expanded register bank.<br>When power up, the address pointer will point to the top address of primary register bank automatically.<br>00H = The address pointer points to the top address of primary register bank (default).<br>AAH = The address pointer points to the top address of expanded register bank. |

## 3.2.2 EXPANDED REGISTER DESCRIPTION

**e-SING:** Single Rail Mode Setting Register (R/W, Expanded Address = 00H)

| Symbol    | Position | Default | Description                                                                                                      |
|-----------|----------|---------|------------------------------------------------------------------------------------------------------------------|
| SING[7:0] | SING.7-0 | 00H     | 0 = Pin TDNn selects single rail mode or dual rail mode. (Default)<br>1 = Single rail mode enabled (with CRSn=0) |

**e-CODE:** Encoder/Decoder Selection Register (R/W, Expanded Address = 01H)

| Symbol    | Position | Default | Description                                                                                                                                                                      |
|-----------|----------|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CODE[7:0] | CODE.7-0 | 00H     | CODEn selects AMI or HDB3 encoder/decoder on a per channel basis with SINGn = 1 and CRSn = 0.<br>0 = HDB3 encoder/decoder enabled. (Default)<br>1 = AMI encoder/decoder enabled. |

**e-CRS:** Clock Recovery Enable/Disable Selection Register (R/W, Expanded Address = 02H)

| Symbol   | Position | Default | Description                                                           |
|----------|----------|---------|-----------------------------------------------------------------------|
| CRS[7:0] | CRS.7-0  | 00H     | 0 = Clock recovery enabled. (Default)<br>1 = Clock recovery disabled. |

**e-RPDN:** Receiver n Powerdown Register (R/W, Expanded Address = 03H)

| Symbol    | Position | Default | Description                                                        |
|-----------|----------|---------|--------------------------------------------------------------------|
| RPDN[7:0] | RPDN.7-0 | 00H     | 0 = Normal operation. (Default)<br>1 = Receiver n is powered down. |

**e-TPDN:** Transmitter n Powerdown Register (R/W, Expanded Address = 04H)

| Symbol    | Position | Default | Description                                                                                                                                                    |
|-----------|----------|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TPDN[7:0] | TPDN.7-0 | 00H     | 0 = Normal operation. (Default)<br>1 = Transmitter n is powered down <sup>(1)</sup> (the corresponding transmit output driver enters a low power high-Z mode). |

<sup>1</sup>: Transmitter n is powered down when either pin TCLKn is pulled low or TPDNn is set to '1'**e-CZER:** Consecutive Zero Detect Enable/Disable Register (R/W, Expanded Address = 05H)

| Symbol    | Position | Default | Description                                                                                                                |
|-----------|----------|---------|----------------------------------------------------------------------------------------------------------------------------|
| CZER[7:0] | CZER.7-0 | 00H     | 0 = Excessive zeros detect disabled. (Default)<br>1 = Excessive zeros detect enabled for HDB3 decoder in single rail mode. |

**e-CODV:** Code Violation Detect Enable/Disable Register (R/W, Expanded Address = 06H)

| Symbol    | Position | Default | Description                                                                                                             |
|-----------|----------|---------|-------------------------------------------------------------------------------------------------------------------------|
| CODV[7:0] | CODV.7-0 | 00H     | 0 = Code Violation Detect enable for HDB3 decoder in single rail mode. (Default)<br>1 = Code Violation Detect disabled. |

**e-EQUA:** Receive Equalizer Enable/Disable Register (R/W, Expanded Address = 07H)

| Symbol    | Position | Default | Description                                                                                                                                                       |
|-----------|----------|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EQUA[7:0] | EQUA.7-0 | 00H     | 0 = Normal operation. (Default)<br>1 = Equalizer in Receiver n is enabled, which can improve the receive performance when transmission length is more than 200 m. |

## 4 IEEE STD 1149.1 JTAG TEST ACCESS PORT

The IDT82V2058 supports the digital Boundary Scan Specification as described in the IEEE 1149.1 standards.

The boundary scan architecture consists of data and instruction registers plus a Test Access Port (TAP) controller. Control of the TAP is achieved through signals applied to the TMS and TCK pins. Data is shifted into the registers via the TDI pin, and shifted out of the registers via the TDO pin. JTAG test data are clocked at a rate determined by JTAG test clock.

The JTAG boundary scan registers includes BSR (Boundary Scan Register), IDR (Device Identification Register), BR (Bypass Register) and IR (Instruction Register). These will be described in the following pages. Refer to [Figure-21](#) for architecture.

### 4.1 JTAG INSTRUCTIONS AND INSTRUCTION REGISTER (IR)

The IR with instruction decode block is used to select the test to be executed or the data register to be accessed or both.

The instructions are shifted in LSB first to this 3-bit register. See [Table-17 Instruction Register Description on page 34](#) for details of the codes and the instructions related.

**Figure-21 JTAG Architecture**

Table-17 Instruction Register Description

| IR Code | Instruction    | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 000     | Extest         | The external test instruction allows testing of the interconnection to other devices. When the current instruction is the EXTEST instruction, the boundary scan register is placed between TDI and TDO. The signal on the input pins can be sampled by loading the boundary scan register using the Capture-DR state. The sampled values can then be viewed by shifting the boundary scan register using the Shift-DR state. The signal on the output pins can be controlled by loading patterns shifted in through input TDI into the boundary scan register using the Update-DR state. |
| 100     | Sample/Preload | The sample instruction samples all the device inputs and outputs. For this instruction, the boundary scan register is placed between TDI and TDO. The normal path between IDT82V2058 logic and the I/O pins is maintained. Primary device inputs and outputs can be sampled by loading the boundary scan register using the Capture-DR state. The sampled values can then be viewed by shifting the boundary scan register using the Shift-DR state.                                                                                                                                     |
| 110     | Idcode         | The identification instruction is used to connect the identification register between TDI and TDO. The device's identification code can then be shifted out using the Shift-DR state.                                                                                                                                                                                                                                                                                                                                                                                                    |
| 111     | Bypass         | The bypass instruction shifts data from input TDI to output TDO with one TCK clock period delay. The instruction is used to bypass the device.                                                                                                                                                                                                                                                                                                                                                                                                                                           |

Table-18 Device Identification Register Description

| Bit No. | Comments        |
|---------|-----------------|
| 0       | Set to '1'      |
| 1~11    | Producer Number |
| 12~27   | Part Number     |
| 28~31   | Device Revision |

## 4.2 JTAG DATA REGISTER

### 4.2.1 DEVICE IDENTIFICATION REGISTER (IDR)

The IDR can be set to define the producer number, part number and the device revision, which can be used to verify the proper version or revision number that has been used in the system under test. The IDR is 32 bits long and is partitioned as in [Table-18](#). Data from the IDR is shifted out to TDO LSB first.

Table-19 Boundary Scan Register Description

| Bit No. | Bit Symbol | Pin Signal | Type | Comments |
|---------|------------|------------|------|----------|
| 0       | POUT0      | LP0        | I/O  |          |
| 1       | PIN0       | LP0        | I/O  |          |
| 2       | POUT1      | LP1        | I/O  |          |
| 3       | PIN1       | LP1        | I/O  |          |
| 4       | POUT2      | LP2        | I/O  |          |
| 5       | PIN2       | LP2        | I/O  |          |
| 6       | POUT3      | LP3        | I/O  |          |
| 7       | PIN3       | LP3        | I/O  |          |
| 8       | POUT4      | LP4        | I/O  |          |
| 9       | PIN4       | LP4        | I/O  |          |
| 10      | POUT5      | LP5        | I/O  |          |
| 11      | PIN5       | LP5        | I/O  |          |
| 12      | POUT6      | LP6        | I/O  |          |
| 13      | PIN6       | LP6        | I/O  |          |
| 14      | POUT7      | LP7        | I/O  |          |
| 15      | PIN7       | LP7        | I/O  |          |

### 4.2.2 BYPASS REGISTER (BR)

The BR consists of a single bit. It can provide a serial path between the TDI input and TDO output, bypassing the BSR to reduce test access times.

### 4.2.3 BOUNDARY SCAN REGISTER (BSR)

The BSR can apply and read test patterns in parallel to or from all the digital I/O pins. The BSR is a 98 bits long shift register and is initialized and read using the instruction EXTEST or SAMPLE/PRELOAD. Each pin is related to one or more bits in the BSR. Please refer to [Table-19](#) for details of BSR bits and their functions.

Table-19 Boundary Scan Register Description (Continued)

| Bit No. | Bit Symbol | Pin Signal | Type | Comments                                                                                                                                                                                                       |
|---------|------------|------------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 16      | PIOS       | N/A        | -    | Controls pins LP[7:0].<br>When '0', the pins are configured as outputs. The output values to the pins are set in POUT 7~0.<br>When '1', the pins are high-Z. The input values to the pins are read in PIN 7~0. |
| 17      | TCLK1      | TCLK1      | I    |                                                                                                                                                                                                                |
| 18      | TDP1       | TDP1       | I    |                                                                                                                                                                                                                |
| 19      | TDN1       | TDN1       | I    |                                                                                                                                                                                                                |
| 20      | RCLK1      | RCLK1      | O    |                                                                                                                                                                                                                |
| 21      | RDP1       | RDP1       | O    |                                                                                                                                                                                                                |

### 4.3 TEST ACCESS PORT CONTROLLER

The TAP controller is a 16-state synchronous state machine. [Figure-22](#) shows its state diagram. A description of each state follows. Note that the figure contains two main branches to access either the data or

instruction registers. The value shown next to each state transition in this figure states the value present at TMS at each rising edge of TCK. Refer to [Table-20](#) for details of the state description.

**Table-20 TAP Controller State Description**

| State            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Test Logic Reset | In this state, the test logic is disabled. The device is set to normal operation. During initialization, the device initializes the instruction register with the IDCODE instruction.<br>Regardless of the original state of the controller, the controller enters the Test-Logic-Reset state when the TMS input is held high for at least 5 rising edges of TCK. The controller remains in this state while TMS is high. The device processor automatically enters this state at power-up.                                                                                                                                           |
| Run-Test/Idle    | This is a controller state between scan operations. Once in this state, the controller remains in the state as long as TMS is held low. The instruction register and all test data registers retain their previous state. When TMS is high and a rising edge is applied to TCK, the controller moves to the Select-DR state.                                                                                                                                                                                                                                                                                                          |
| Select-DR-Scan   | This is a temporary controller state and the instruction does not change in this state. The test data register selected by the current instruction retains its previous state. If TMS is held low and a rising edge is applied to TCK when in this state, the controller moves into the Capture-DR state and a scan sequence for the selected test data register is initiated. If TMS is held high and a rising edge applied to TCK, the controller moves to the Select-IR-Scan state.                                                                                                                                                |
| Capture-DR       | In this state, the Boundary Scan Register captures input pin data if the current instruction is EXTEST or SAMPLE/PRELOAD. The instruction does not change in this state. The other test data registers, which do not have parallel input, are not changed. When the TAP controller is in this state and a rising edge is applied to TCK, the controller enters the Exit1-DR state if TMS is high or the Shift-DR state if TMS is low.                                                                                                                                                                                                 |
| Shift-DR         | In this controller state, the test data register connected between TDI and TDO as a result of the current instruction shifts data on stage toward its serial output on each rising edge of TCK. The instruction does not change in this state. When the TAP controller is in this state and a rising edge is applied to TCK, the controller enters the Exit1-DR state if TMS is high or remains in the Shift-DR state if TMS is low.                                                                                                                                                                                                  |
| Exit1-DR         | This is a temporary state. While in this state, if TMS is held high, a rising edge applied to TCK causes the controller to enter the Update-DR state, which terminates the scanning process. If TMS is held low and a rising edge is applied to TCK, the controller enters the Pause-DR state. The test data register selected by the current instruction retains its previous value and the instruction does not change during this state.                                                                                                                                                                                           |
| Pause-DR         | The pause state allows the test controller to temporarily halt the shifting of data through the test data register in the serial path between TDI and TDO. For example, this state could be used to allow the tester to reload its pin memory from disk during application of a long test sequence. The test data register selected by the current instruction retains its previous value and the instruction does not change during this state. The controller remains in this state as long as TMS is low. When TMS goes high and a rising edge is applied to TCK, the controller moves to the Exit2-DR state.                      |
| Exit2-DR         | This is a temporary state. While in this state, if TMS is held high, a rising edge applied to TCK causes the controller to enter the Update-DR state, which terminates the scanning process. If TMS is held low and a rising edge is applied to TCK, the controller enters the Shift-DR state. The test data register selected by the current instruction retains its previous value and the instruction does not change during this state.                                                                                                                                                                                           |
| Update-DR        | The Boundary Scan Register is provided with a latched parallel output to prevent changes while data is shifted in response to the EXTEST and SAMPLE/PRELOAD instructions. When the TAP controller is in this state and the Boundary Scan Register is selected, data is latched into the parallel output of this register from the shift-register path on the falling edge of TCK. The data held at the latched parallel output changes only in this state. All shift-register stages in the test data register selected by the current instruction retain their previous value and the instruction does not change during this state. |
| Select-IR-Scan   | This is a temporary controller state. The test data register selected by the current instruction retains its previous state. If TMS is held low and a rising edge is applied to TCK when in this state, the controller moves into the Capture-IR state, and a scan sequence for the instruction register is initiated. If TMS is held high and a rising edge is applied to TCK, the controller moves to the Test-Logic-Reset state. The instruction does not change during this state.                                                                                                                                                |
| Capture-IR       | In this controller state, the shift register contained in the instruction register loads a fixed value of '100' on the rising edge of TCK. This supports fault-isolation of the board-level serial test data path. Data registers selected by the current instruction retain their value and the instruction does not change during this state. When the controller is in this state and a rising edge is applied to TCK, the controller enters the Exit1-IR state if TMS is held high, or the Shift-IR state if TMS is held low.                                                                                                     |
| Shift-IR         | In this state, the shift register contained in the instruction register is connected between TDI and TDO and shifts data one stage towards its serial output on each rising edge of TCK. The test data register selected by the current instruction retains its previous value and the instruction does not change during this state. When the controller is in this state and a rising edge is applied to TCK, the controller enters the Exit1-IR state if TMS is held high, or remains in the Shift-IR state if TMS is held low.                                                                                                    |

Table-20 TAP Controller State Description (Continued)

| State     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Exit1-IR  | This is a temporary state. While in this state, if TMS is held high, a rising edge applied to TCK causes the controller to enter the Update-IR state, which terminates the scanning process. If TMS is held low and a rising edge is applied to TCK, the controller enters the Pause-IR state. The test data register selected by the current instruction retains its previous value and the instruction does not change during this state. |
| Pause-IR  | The pause state allows the test controller to temporarily halt the shifting of data through the instruction register. The test data register selected by the current instruction retains its previous value and the instruction does not change during this state. The controller remains in this state as long as TMS is low. When TMS goes high and a rising edge is applied to TCK, the controller moves to the Exit2-IR state.          |
| Exit2-IR  | This is a temporary state. While in this state, if TMS is held high, a rising edge applied to TCK causes the controller to enter the Update-IR state, which terminates the scanning process. If TMS is held low and a rising edge is applied to TCK, the controller enters the Shift-IR state. The test data register selected by the current instruction retains its previous value and the instruction does not change during this state. |
| Update-IR | The instruction shifted into the instruction register is latched into the parallel output from the shift-register path on the falling edge of TCK. When the new instruction has been latched, it becomes the current instruction. The test data registers selected by the current instruction retain their previous value.                                                                                                                  |

Компания «Life Electronics» занимается поставками электронных компонентов импортного и отечественного производства от производителей и со складов крупных дистрибьюторов Европы, Америки и Азии.

С конца 2013 года компания активно расширяет линейку поставок компонентов по направлению коаксиальный кабель, кварцевые генераторы и конденсаторы (керамические, пленочные, электролитические), за счёт заключения дистрибьюторских договоров

Мы предлагаем:

- Конкурентоспособные цены и скидки постоянным клиентам.
- Специальные условия для постоянных клиентов.
- Подбор аналогов.
- Поставку компонентов в любых объемах, удовлетворяющих вашим потребностям.
- Приемлемые сроки поставки, возможна ускоренная поставка.
- Доставку товара в любую точку России и стран СНГ.
- Комплексную поставку.
- Работу по проектам и поставку образцов.
- Формирование склада под заказчика.
- Сертификаты соответствия на поставляемую продукцию (по желанию клиента).
- Тестирование поставляемой продукции.
- Поставку компонентов, требующих военную и космическую приемку.
- Входной контроль качества.
- Наличие сертификата ISO.

В составе нашей компании организован Конструкторский отдел, призванный помогать разработчикам, и инженерам.

Конструкторский отдел помогает осуществить:

- Регистрацию проекта у производителя компонентов.
- Техническую поддержку проекта.
- Защиту от снятия компонента с производства.
- Оценку стоимости проекта по компонентам.
- Изготовление тестовой платы монтаж и пусконаладочные работы.
