General Description

The MAX7030 crystal-based, fractional-N transceiver is designed to transmit and receive ASK/OOK data at factory-preset carrier frequencies of 315MHz or 433.92MHz with data rates up to 33kbps (Manchester encoded) or 66kbps (NRZ encoded). This device generates a typical output power of +10dBm into a 50Ω load and exhibits typical sensitivity of -114dBm. The MAX7030 features separate transmit and receive pins (PAOUT and LNAIN) and provides an internal RF switch that can be used to connect the transmit and receive pins to a common antenna.

The MAX7030 transmit frequency is generated by a 16 bit, fractional-N, phase-locked loop (PLL), while the receiver's local oscillator (LO) is generated by an integer-N PLL. This hybrid architecture eliminates the need for separate transmit and receive crystal reference oscillators because the fractional-N PLL is preset to be 10.7MHz above the receive LO. Retaining the fixed-N PLL for the receiver avoids the higher current-drain requirements of a fractional-N PLL and keeps the receiver current drain as low as possible. All frequencygeneration components are integrated on-chip, and only a crystal, a 10.7MHz IF filter, and a few discrete components are required to implement a complete antenna/digital data solution.

The MAX7030 is available in a small, 5mm x 5mm, 32 pin thin QFN package, and is specified to operate over the automotive -40°C to +125°C temperature range.

Features

♦ **+2.1V to +3.6V or +4.5V to +5.5V Single-Supply Operation**

MAXM

- ♦ **Single-Crystal Transceiver**
- ♦ **Factory-Preset Frequency (No Serial Interface Required)**
- ♦ **ASK/OOK Modulation**
- ♦ **+10dBm Output Power into 50**Ω **Load**
- ♦ **Integrated TX/RX Switch**
- ♦ **Integrated Transmit and Receive PLL, VCO, and Loop Filter**
- ♦ **> 45dB Image Rejection**
- ♦ **Typical RF Sensitivity*: -114dBm**
- ♦ **Selectable IF Bandwidth with External Filter**
- ♦ **< 12.5mA Transmit-Mode Current**
- ♦ **< 6.7mA Receive-Mode Current**
- ♦ **< 800nA Shutdown Current**
- ♦ **Fast-On Startup Feature, < 250µs**
- ♦ **Small, 32-Pin, Thin QFN Package**

*0.2% BER, 4kbps Manchester-encoded data, 280kHz IF BW

ABSOLUTE MAXIMUM RATINGS

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

DC ELECTRICAL CHARACTERISTICS

(Typical Application Circuit, 50Ω system impedance, VAVDD = V_{DVDD} = V_{HVIN} = V_{PAVDD} = +2.1V to +3.6V, f_{RF} = 315MHz or 433.92MHz, T_A = -40°C to +125°C, unless otherwise noted. Typical values are at V_{AVDD} = V_{DVDD} = V_{HVIN} = V_{PAVDD} = +2.7V, $T_A = +25^{\circ}$ C, unless otherwise noted.) (Note 1)

DC ELECTRICAL CHARACTERISTICS (continued)

(Typical Application Circuit, 50Ω system impedance, V_{AVDD} = V_{DVDD} = V_{HVIN} = V_{PAVDD} = +2.1V to +3.6V, f_{RF} = 315MHz or 433.92MHz, T_A = -40°C to +125°C, unless otherwise noted. Typical values are at V_{AVDD} = V_{DVDD} = V_{HVIN} = V_{PAVDD} = +2.7V, $T_A = +25^{\circ}$ C, unless otherwise noted.) (Note 1)

AC ELECTRICAL CHARACTERISTICS

(Typical Application Circuit, 50Ω system impedance, VPAVDD = VAVDD = VDVDD = VHVIN = +2.1V to +3.6V, fRF = 315MHz or 433.92MHz, T_A = -40°C to +125°C, unless otherwise noted. Typical values are at V_{PAVDD} = V_{AVDD} = V_{DVDD} = V_{HVIN} = +2.7V, $T_A = +25^{\circ}$ C, unless otherwise noted.) (Note 1)

AC ELECTRICAL CHARACTERISTICS (continued)

(Typical Application Circuit, 50Ω system impedance, V_{PAVDD} = V_{AVDD} = V_{DVDD} = V_{HVIN} = +2.1V to +3.6V, f_{RF} = 315MHz or 433.92MHz, T_A = -40°C to +125°C, unless otherwise noted. Typical values are at VpAvDD = VAvDD = VDVDD = VHVIN = +2.7V, $T_A = +25^{\circ}$ C, unless otherwise noted.) (Note 1)

AC ELECTRICAL CHARACTERISTICS (continued)

(Typical Application Circuit, 50 Ω system impedance, VPAVDD = VAVDD = V_{HVIN} = +2.1V to +3.6V, f_{RF} = 315MHz or 433.92 MHz, T_A = -40°C to +125°C, unless otherwise noted. Typical values are at VPAVDD = VAVDD = VDVDD = VHVIN = +2.7V, $T_A = +25^{\circ}$ C, unless otherwise noted.) (Note 1)

Note 1: Supply current, output power, and efficiency are greatly dependent on board layout and PAOUT match.

Note 2: 100% tested at T_A = +125°C. Guaranteed by design and characterization overtemperature.

Note 3: 50% duty cycle at 10kHz ASK data (Manchester coded).

Note 4: Guaranteed by design and characterization. Not production tested.

Note 5: Time for final signal detection; does not include baseband filter settling.

Note 6: Efficiency = P OUT/ $(V_{DD} \times I_{DD})$.

Note 7: Dependent on PCB trace capacitance.

Note 8: Input impedance is measured at the LNAIN pin. Note that the impedance at 315MHz includes the 12nH inductive degeneration from the LNA source to ground. The impedance at 434MHz includes a 10nH inductive degeneration connected from the LNA source to ground. The equivalent input circuit is 50Ω in series with ~2.2pF. The voltage conversion is measured with the LNA input-matching inductor, the degeneration inductor, and the LNA/mixer tank in place, and does not include the IF filter insertion loss.

Typical Operating Characteristics

(Typical Application Circuit, VPAVDD = VAVDD = VDVDD = VHVIN = +3.0V, f_{RF} = 433.92MHz, IF BW = 280kHz, 4kbps Manchester encoded, 0.2% BER, $T_A = +25^{\circ}C$, unless otherwise noted.)

Pin Description

Pin Description (continued)

Detailed Description

The MAX7030 315MHz and 433.92MHz CMOS transceiver and a few external components provide a complete transmit and receive chain from the antenna to the digital data interface. This device is designed for transmitting and receiving ASK data. All transmit frequencies are generated by a fractional-N-based synthesizer, allowing for very fine frequency steps in increments of fXTAL/4096. The receive LO is generated by a traditional integer-N-based synthesizer. Depending on component selection, data rates as high as 33kbps (Manchester encoded) or 66kbps (NRZ encoded) can be achieved.

Receiver

Low-Noise Amplifier (LNA)

The LNA is a cascode amplifier with off-chip inductive degeneration that achieves approximately 30dB of voltage gain that is dependent on both the antenna-matching network at the LNA input and the LC tank network between the LNA output and the mixer inputs.

The off-chip inductive degeneration is achieved by connecting an inductor from LNASRC to GND. This inductor sets the real part of the input impedance at LNAIN, allowing for a more flexible match for low-input impedances such as a PCB trace antenna. A nominal value for this inductor with a 50Ω input impedance is 12nH at 315MHz and 10nH at 434MHz, but the inductance is affected by PCB trace length. LNASRC can be shorted to ground to increase sensitivity by approximately 1dB, but the input match must then be reoptimized.

The LC tank filter connected to LNAOUT consists of L5 and C9 (see the Typical Application Circuit). Select L5 and C9 to resonate at the desired RF input frequency. The resonant frequency is given by:

$$
f = \frac{1}{2\pi\sqrt{L_{\text{TOTAL}} \times C_{\text{TOTAL}}}}
$$

where $L_{\text{TOTAL}} = L5 + L_{\text{PARASITICS}}$ and $C_{\text{TOTAL}} = C9 +$ CPARASITICS.

LPARASITICS and CPARASITICS include inductance and capacitance of the PCB traces, package pins, mixerinput impedance, LNA-output impedance, etc. These parasitics at high frequencies cannot be ignored, and can have a dramatic effect on the tank filter center frequency. Lab experimentation should be done to optimize the center frequency of the tank. The total parasitic capacitance is generally between 5pF and 7pF.

Automatic Gain Control (AGC)

When the AGC is enabled, it monitors the RSSI output. When the RSSI output reaches 1.28V, which corresponds to an RF input level of approximately -55dBm, the AGC switches on the LNA gain-reduction attenuator. The attenuator reduces the LNA gain by 36dB, thereby reducing the RSSI output by about 540mV to 740mV. The LNA resumes high-gain mode when the RSSI output level drops back below 680mV (approximately -59dBm at the RF input) for a programmable interval called the AGC dwell time (see Table 1). The AGC has a hysteresis of approximately 4dB. With the AGC function, the RSSI dynamic range is increased, allowing the MAX7030 to reliably produce an ASK output for RF input levels up to 0dBm with a modulation depth of 18dB. AGC is not required and can be disabled (see Table 1).

Table 1. AGC Dwell Time Settings for MAX7030

AGC Dwell-Time Settings

The AGC dwell timer holds the AGC in low-gain state for a set amount of time after the power level drops below the AGC switching threshold. After that set amount of time, if the power level is still below the AGC threshold, the LNA goes into high-gain state. This is important for ASK since the modulated data may have a high level above the threshold and low level below the threshold, which without the dwell timer would cause the AGC to switch on every bit.

The MAX7030 uses the three AGC control pins (AGC0, AGC1, AGC2) to set seven user-controlled, dwell-timer settings. The AGC dwell time is dependent on the crystal frequency and the bit settings of the AGC control pins. To calculate the dwell time, use the following equation:

$$
Dwell Time = \frac{2^{K}}{f_{\text{XTAL}}}
$$

where K is an odd integer in decimal from 11 to 23, determined by the control pin settings shown in Table 1.

To calculate the value of K, use the following equation and use the next integer higher than the calculated result:

$$
K \geq 3.3 \times \log_{10} \text{(Dwell Time x f_{\text{XTAL}})}
$$

For Manchester Code (50% duty cycle), set the dwell time to at least twice the bit period. For nonreturn-tozero (NRZ) data, set the dwell to greater than the period of the longest string of zeros or ones. For example, using Manchester Code at 315MHz $(fXTAL)$ = 12.679MHz) with a data rate of 2kbps (bit period $=$ 250µs), the dwell time needs to be greater than 500µs:

K ≥ 3.3 x log10 (500µs x 12.679) ≈ 12.546

Choose the AGC pin settings for K to be the next oddinteger value higher than 12.546, which is 13. This says that AGC1 is set high and AGC0 and AGC2 are set low.

A unique feature of the MAX7030 is the integrated image rejection of the mixer. This eliminates the need for a costly front-end SAW filter for many applications. The advantage of not using a SAW filter is increased sensitivity, simplified antenna matching, less board space, and lower cost.

The mixer cell is a pair of double-balanced mixers that perform an IQ downconversion of the RF input to the 10.7MHz intermediate frequency (IF) with low-side injection (i.e., $f_{LO} = f_{RF} - f_{IF}$). The image-rejection circuit then combines these signals to achieve a typical 46dB of image rejection over the full temperature range. Lowside injection is required as high-side injection is not possible due to the on-chip image rejection. The IF output is driven by a source follower, biased to create a driving impedance of 330 Ω to interface with an off-chip 330Ω ceramic IF filter. The voltage-conversion gain driving a 330Ω load is approximately 20dB. Note that the MIXIN+ and MIXIN- inputs are functionally identical.

Integer-N Phase-Locked Loop (PLL)

The MAX7030 utilizes a fixed-integer-N PLL to generate the receive LO. All PLL components, including the loop filter, voltage-controlled oscillator, charge pump, asynchronous 24x divider, and phase-frequency detector are integrated internally. The loop bandwidth is approximately 500kHz. The relationship between RF, IF, and crystal reference frequencies is given by:

$$
f_{\text{XTAL}} = (f_{\text{RF}} - f_{\text{IF}})/24
$$

MAX7030 MAX7030

Intermediate Frequency (IF)

The IF section presents a differential 330 $Ω$ load to provide matching for the off-chip ceramic filter. The internal six AC-coupled limiting amplifiers produce an overall gain of approximately 65dB, with a bandpass filter type response centered near the 10.7MHz IF frequency with a 3dB bandwidth of approximately 10MHz. For ASK data, the RSSI circuit demodulates the IF to baseband by producing a DC output proportional to the log of the IF signal level with a slope of approximately 15mV/dB.

Data Filter

The data filter for the demodulated data is implemented as a 2nd-order, lowpass, Sallen-Key filter. The pole locations are set by the combination of two on-chip resistors and two external capacitors. Adjusting the value of the external capacitors changes the corner frequency to optimize for different data rates. Set the corner frequency in kHz to approximately 3 times the fastest expected Manchester data rate in kbps from the transmitter (1.5 times the fastest expected NRZ data rate). Keeping the corner frequency near the data rate rejects any noise at higher frequencies, resulting in an increase in receiver sensitivity.

The configuration shown in Figure 1 can create a Butterworth or Bessel response. The Butterworth filter offers a very-flat-amplitude response in the passband and a rolloff rate of 40dB/decade for the two-pole filter. The Bessel filter has a linear phase response, which works well for filtering digital data. To calculate the value of the capacitors, use the following equations, along with the coefficients in Table 2:

$$
C_{F1} = \frac{b}{a(100k\Omega)(\pi)(f_C)}
$$

$$
C_{F2} = \frac{a}{4(100k\Omega)(\pi)(f_C)}
$$

where f_C is the desired 3dB corner frequency.

For example, choose a Butterworth filter response with a corner frequency of 5kHz:

Choosing standard capacitor values changes CF1 to 470pF and C_{F2} to 220pF. In the Typical Application Circuit, C_{F1} and C_{F2} are named C₁₆ and C₁₇, respectively.

Data Slicer The data slicer takes the analog output of the data filter and converts it to a digital signal. This is achieved by using a comparator and comparing the analog input to a threshold voltage. The threshold voltage is set by the voltage on the DS- pin, which is connected to the negative input of the data slicer comparator.

Numerous configurations can be used to generate the data-slicer threshold. For example, the circuit in Figure 2 shows a simple method using only one resistor and one capacitor. This configuration averages the analog output of the filter and sets the threshold to approximately 50% of that amplitude. With this configuration, the threshold automatically adjusts as the analog signal varies, minimizing the possibility for errors in the digital data. The values of R and C affect how fast the threshold tracks the analog amplitude. Be sure to keep the corner frequency of the RC circuit much lower (about 10 times) than the lowest expected data rate.

With this configuration, a long string of NRZ zeros or ones can cause the threshold to drift. This configuration works best if a coding scheme, such as Manchester coding, which has an equal number of zeros and ones, is used.

Figure 3 shows a configuration that uses the positive and negative peak detectors to generate the threshold. This configuration sets the threshold to the midpoint between a high output and a low output of the data filter.

Figure 1. Sallen-Key Lowpass Data Filter

Table 2. Coefficients to Calculate CF1 and CF2

Figure 2. Generating Data-Slicer Threshold Using a Lowpass Filter

Peak Detectors

The maximum peak detector (PDMAX) and minimum peak detector (PDMIN), with resistors and capacitors shown in Figure 3, create DC output voltages equal to the high- and low-peak values of the filtered demodulated signal. The resistors provide a path for the capacitors to discharge, allowing the peak detectors to dynamically follow peak changes of the data filter output voltages.

The maximum and minimum peak detectors can be used together to form a data slicer threshold voltage at a value midway between the maximum and minimum voltage levels of the data stream (see the Data Slicer section and Figure 3). Set the RC time constant of the peak detector combining network to at least 5 times the data period.

If there is an event that causes a significant change in the magnitude of the baseband signal, such as an AGC gain-switch or a power-up transient, the peak detectors may "catch" a false level. If a false peak is detected, the slicing level is incorrect. The MAX7030 peak detectors correct these problems by temporarily tracking the incoming baseband filter voltage when an AGC state switch occurs, or forcing the peak detectors to track the baseband filter output voltage until all internal circuits are stable following an enable pin low-to-high transition and also T/\overline{R} pin high-to-low transition. The peak detectors exhibit a fast attack/slow decay response. This feature allows for an extremely fast startup or AGC recovery.

Transmitter

Power Amplifier (PA)

The PA of the MAX7030 is a high-efficiency, opendrain, switch-mode amplifier. The PA with proper output-matching network can drive a wide range of antenna impedances, which includes a small-loop PCB trace and a 50Ω antenna. The output-matching network

Figure 3. Generating Data-Slicer Threshold Using the Peak **Detectors**

for a 50Ω antenna is shown in the Typical Application Circuit. The output-matching network suppresses the carrier harmonics and transforms the antenna impedance to an optimal impedance at PAOUT (pin 5). The optimal impedance at PAOUT is between 100 Ω and 150Ω to transmit +10dBm with a 2.7V supply.

When the output-matching network is properly tuned, the PA transmits power with a high overall efficiency of up to 32%. The efficiency of the PA itself is more than 46%. The output power is set by an external resistor at PAOUT and is also dependent on the external antenna and antenna-matching network at the PA output.

Envelope Shaping

The MAX7030 features an internal envelope-shaping resistor, which connects between the open-drain output of the PA and the power supply (see the Typical Application Circuit). The envelope-shaping resistor slows the turn-on/turn-off of the PA in ASK mode and results in a smaller spectral width of the modulated PA output signal.

Fractional-N Phase-Locked Loop (PLL)

The MAX7030 utilizes a fully integrated, fractional-N, PLL for its transmit frequency synthesizer. All PLL components, including the loop filter, are integrated internally. The loop bandwidth is approximately 200kHz.

Power-Supply Connections

The MAX7030 can be powered from a 2.1V to 3.6V supply or a 4.5V to 5.5V supply. If a 4.5V to 5.5V supply is used, then the on-chip linear regulator reduces the 5V supply to the 3V needed to operate the chip.

To operate the MAX7030 from a 3V supply, connect PAVDD, AVDD, DVDD, and HVIN to the 3V supply. When using a 5V supply, connect the supply to HVIN

only and connect AVDD, PAVDD, and DVDD together. In both cases, bypass DVDD, HVIN, and PAVDD to GND with 0.01µF and 220pF capacitors and bypass AVDD to GND with 0.1µF and 220pF capacitors. Bypass T/R, ENABLE, DATA, and AGC0-2 with 10pF capacitors to GND. Place all bypass capacitors as close as possible to the respective pins.

Transmit/Receive **Antenna Switch**

The MAX7030 features an internal SPST RF switch that, when combined with a few external components, allows the transmit and receive pins to share a common antenna (see the Typical Application Circuit). In receive mode, the switch is open and the power amplifier is shut down, presenting a high impedance to minimize the loading of the LNA. In transmit mode, the switch closes to complete a resonant tank circuit at the PA output and forms an RF short at the input to the LNA. In this mode, the external passive components couple the output of the PA to the antenna and protect the LNA input from strong transmitted signals.

The switch state is controlled by the T/\overline{R} pin (pin 22). Drive T/\overline{R} high to put the device in transmit mode; drive T/\overline{R} low to put the device in receive mode.

Control Interface Considerations

When operating the MAX7030 with a +4.5V to +5.5V supply voltage, the AGC0, ACG1, AGC2, DATA, ENABLE and $\overline{T/R}$ pins may be driven by a microcontroller with either 3V or 5V interface logic levels. When operating the MAX7030 with a $+2.1V$ to $+3.6V$ supply, the microcontroller must produce logic levels which conform to the V_{IH} and V_{IL} specifications in the DC Electrical Characteristics for the MAX7030.

Crystal Oscillator (XTAL)

The XTAL oscillator in the MAX7030 is designed to present a capacitance of approximately 3pF between the XTAL1 and XTAL2 pins. In most cases, this corresponds to a 4.5pF load capacitance applied to the external crystal when typical PCB parasitics are added. **It is very important to use a crystal with a load capacitance that is equal to the capacitance of the MAX7030 crystal oscillator plus PCB parasitics**. If a crystal designed to oscillate with a different load capacitance is used, the crystal is pulled away from its stated operating frequency, introducing an error in the reference frequency. Crystals designed to operate with higher differential load capacitance always pull the reference frequency higher.

In actuality, the oscillator pulls every crystal. The crystal's natural frequency is really below its specified frequency, but when loaded with the specified load capacitance, the crystal is pulled and oscillates at its specified frequency. This pulling is already accounted for in the specification of the load capacitance.

Additional pulling can be calculated if the electrical parameters of the crystal are known. The frequency pulling is given by:

$$
f_{\rm P} = \frac{C_{\rm m}}{2} \left(\frac{1}{C_{\rm CASE} + C_{\rm LOAD}} - \frac{1}{C_{\rm CASE} + C_{\rm SPEC}} \right) \times 10^6
$$

where:

fp is the amount the crystal frequency is pulled in ppm.

C_m is the motional capacitance of the crystal.

CCASE is the case capacitance.

C_{SPFC} is the specified load capacitance.

CLOAD is the actual load capacitance.

When the crystal is loaded as specified, i.e., CLOAD = CSPEC, the frequency pulling equals zero.

Pin Configuration

 Компания «Life Electronics» занимается поставками электронных компонентов импортного и отечественного производства от производителей и со складов крупных дистрибьюторов Европы, Америки и Азии.

С конца 2013 года компания активно расширяет линейку поставок компонентов по направлению коаксиальный кабель, кварцевые генераторы и конденсаторы (керамические, пленочные, электролитические), за счёт заключения дистрибьюторских договоров

 Мы предлагаем:

- *Конкурентоспособные цены и скидки постоянным клиентам.*
- *Специальные условия для постоянных клиентов.*
- *Подбор аналогов.*
- *Поставку компонентов в любых объемах, удовлетворяющих вашим потребностям.*
- *Приемлемые сроки поставки, возможна ускоренная поставка.*
- *Доставку товара в любую точку России и стран СНГ.*
- *Комплексную поставку.*
- *Работу по проектам и поставку образцов.*
- *Формирование склада под заказчика.*
- *Сертификаты соответствия на поставляемую продукцию (по желанию клиента).*
- *Тестирование поставляемой продукции.*
- *Поставку компонентов, требующих военную и космическую приемку.*
- *Входной контроль качества.*
- *Наличие сертификата ISO.*

 В составе нашей компании организован Конструкторский отдел, призванный помогать разработчикам, и инженерам.

Конструкторский отдел помогает осуществить:

- *Регистрацию проекта у производителя компонентов.*
- *Техническую поддержку проекта.*
- *Защиту от снятия компонента с производства.*
- *Оценку стоимости проекта по компонентам.*
- *Изготовление тестовой платы монтаж и пусконаладочные работы.*
