

36 Mb (1M x 36 & 2M x 18) DDR-II (Burst of 4) CIO Synchronous SRAMs

JANUARY 2009

Features

- 1M x 36 or 2M x 18.
- On-chip delay-locked loop (DLL) for wide data valid window.
- Common I/O read and write ports.
- Synchronous pipeline read with late write operation.
- Double data rate (DDR-II) interface for read and write input ports.
- Fixed 4-bit burst for read and write operations.
- Clock stop support.
- Two input clocks (K and $\bar{K}$) for address and control registering at rising edges only.
- Two input clocks (C and $\bar{C}$) for data output control.
- Two echo clocks (CQ and $\bar{CQ}$) that are delivered simultaneously with data.
- +1.8V core power supply and 1.5, 1.8V V_{DDQ} , used with 0.75, 0.9V V_{REF}
- HSTL input and output levels.
- Registered addresses, write and read controls, byte writes, and data outputs.
- Full data coherency.
- Boundary scan using limited set of JTAG 1149.1 functions.
- Byte write capability.
- Fine ball grid array (FBGA) package
 - 15mm x 17mm body size
 - 1mm pitch
 - 165-ball (11 x 15) array
- Programmable impedance output drivers via 5x user-supplied precision resistor.

Description

The 36Mb IS61DDB41M36 and IS61DDB42M18 are synchronous, high-performance CMOS static random access memory (SRAM) devices. These SRAMs have a common I/O bus. The rising edge of K clock initiates the read/write operation, and all internal operations are self-timed. Refer to the *Timing Reference Diagram for Truth Table on p.8* for a description of the basic operations of these DDR-II (Burst of 4) CIO SRAMs.

Read and write addresses are registered on alternating rising edges of the K clock. Reads and writes are performed in double data rate. The following are registered internally on the rising edge of the K clock:

- Read and write addresses
- Address load
- Read/write enable
- Byte writes for burst addresses 1 and 3
- Data-in for burst addresses 1 and 3

The following are registered on the rising edge of the $\bar{K}$ clock:

- Byte writes for burst addresses 2 and 4

- Data-in for burst addresses 2 and 4

Byte writes can change with the corresponding data-in to enable or disable writes on a per-byte basis. An internal write buffer enables the data-ins to be registered one cycle later than the write address. The first data-in burst is clocked one cycle later than the write command signal, and the second burst is timed to the following rising edge of the $\bar{K}$ clock. Two full clock cycles are required to complete a write operation.

During the burst read operation, at the first and third bursts the data-outs are updated from output registers off the second and fourth rising edges of the $\bar{C}$ clock (starting 1.5 cycles later). At the second and fourth bursts, the data-outs are updated with the third and fifth rising edges of the corresponding C clock (see page 9). The K and $\bar{K}$ clocks are used to time the data-outs whenever the C and $\bar{C}$ clocks are tied high. Two full clock cycles are required to complete a read operation

The device is operated with a single +1.8V power supply and is compatible with HSTL I/O interfaces.

SRAM Features

Read Operations

The SRAM operates continuously in a burst-of-four mode. Read cycles are started by registering $R/\overline{W}$ in active high state at the rising edge of the K clock. $R/\overline{W}$ can be activated every other cycle because two full cycles are required to complete the burst-of-four read in DDR mode. A second set of clocks, C and $\overline{C}$, are used to control the timing to the outputs. A set of free-running echo clocks, CQ and $\overline{CQ}$, are produced internally with timings identical to the data-outs. The echo clocks can be used as data capture clocks by the receiver device.

When the C and $\overline{C}$ clocks are connected high, the K and $\overline{K}$ clocks assume the function of those clocks. In this case, the data corresponding to the first address is clocked 1.5 cycles later by the rising edge of the $\overline{K}$ clock. The data corresponding to the second burst is clocked 2 cycles later by the following rising edge of the K clock. The third data-out is clocked by the subsequent rising edge of the $\overline{K}$ clock, and the fourth data-out is clocked by the subsequent rising edge of the K clock.

Whenever $\overline{LD}$ is low, a new address is registered at the rising edge of the K clock. A NOP operation ($\overline{LD}$ is high) does not terminate the previous read. The output drivers disable automatically to a high state.

Write Operations

Write operations can also be initiated at every other rising edge of the K clock whenever $R/\overline{W}$ is low. The write address is also registered at that time. When the address needs to change, $\overline{LD}$ needs to be low simultaneously to be registered by the rising edge of K. Again, the write always occurs in bursts of four.

The write data is provided in a 'late write' mode; that is, the data-in corresponding to the first address of the burst, is presented 1 cycle later or at the rising edge of the following K clock. The data-in corresponding to the second write burst address follows next, registered by the rising edge of $\bar{K}$. The third data-out is clocked by the subsequent rising edge of the K clock, and the fourth data-out is clocked by the subsequent rising edge of the $\bar{K}$ clock.

The data-in provided for writing is initially kept in write buffers. The information on these buffers is written into the array on the third write cycle. A read cycle to the last two write address produces data from the write buffers. The SRAM maintains data coherency.

During a write, the byte writes independently control which byte of any of the four burst addresses is written (see *X18/X36 Write Truth Tables* on page 9 and *Timing Reference Diagram for Truth Table* on page 8).

Whenever a write is disabled ($R/\bar{W}$ is high at the rising edge of K), data is not written into the memory.

RQ Programmable Impedance

An external resistor, RQ, must be connected between the ZQ pin on the SRAM and V_{SS} to enable the SRAM to adjust its output driver impedance. The value of RQ must be 5x the value of the intended line impedance driven by the SRAM. For example, an RQ of 250 Ω results in a driver impedance of 50 Ω . The allowable range of RQ to guarantee impedance matching is between 175 Ω and 350 Ω , with the tolerance described in *Programmable Impedance Output Driver DC Electrical Characteristics* on page 15. The RQ resistor should be placed less than two inches away from the ZQ ball on the SRAM module. The capacitance of the loaded ZQ trace must be less than 3 pF.

The ZQ pin can also be directly connected to V_{DDQ} to obtain a minimum impedance setting. ZQ must never be connected to V_{SS} .

Programmable Impedance and Power-Up Requirements

Periodic readjustment of the output driver impedance is necessary as the impedance is greatly affected by drifts in supply voltage and temperature. At power-up, the driver impedance is in the middle of allowable impedances values. The final impedance value is achieved within 1024 clock cycles.

Clock Consideration

This device uses an internal DLL for maximum output data valid window. It can be placed in a stopped-clock mode to minimize power and requires only 1024 cycles to restart.

No clocks can be issued until V_{DD} reaches its allowable operating range.

Single Clock Mode

This device can be also operated in single-clock mode. In this case, C and $\bar{C}$ are both connected high at power-up and must never change. Under this condition, K and $\bar{K}$ control the output timings.

Either clock pair must have both polarities switching and must never connect to V_{REF} , as they are not differential clocks.

The following figure depicts an implementation of four 2M x 18 DDR-II SRAMs with common I/Os. In this application example, the second pair of C and $\overline{C}$ clocks is delayed such that the return data meets the data setup and hold times at the bus master.

1. The power-down sequence must be done in reverse of the power-up sequence.
2. VDDQ can be allowed to exceed VDD by no more than 0.6V.
3. VREF can be applied concurrently with VDDQ.

State Diagram

The *Timing Reference Diagram for Truth Table* on page 8 is helpful in understanding the clock and write truth tables, as it shows the cycle relationship between clocks, address, data-in, data-out, and controls. All read and write commands are issued at the beginning of cycles t and t_w , respectively.

Notes:

1. The internal burst counter is always fixed as two-bit.
2. X = don't care; H = logic "1"; L = logic "0".
3. A read operation is started when control signal R/ $\bar{W}$ is active high.
4. A write operation is started when control signal R/ $\bar{W}$ is active low.
5. Before entering into the stop clock, all pending read and write commands must be completed.
6. For timing definitions, refer to the *AC Characteristics* on page 16. Signals must have AC specifications at timings indicated in parenthesis with respect to switching clocks K, $\bar{K}$, C, and $\bar{C}$.

3. JEDEC Standard JESD8-6 Class 1 compatible.
4. For JTAG inputs only.
5. Currents are estimates only and need to be verified.

Typical AC Input Characteristics

Item	Symbol	Minimum	Maximum	Notes
AC input logic high	$V_{IH} (ac)$	$V_{REF} + 0.4$		1, 2, 3, 4
AC input logic low	$V_{IL} (ac)$		$V_{REF} - 0.4$	1, 2, 3, 4
Clock input logic high ($K, \bar{K}, C, \bar{C}$)	$V_{IH-CLK} (ac)$	$V_{REF} + 0.4$		1, 2, 3
Clock input logic low ($K, \bar{K}, C, \bar{C}$)	$V_{IL-CLK} (ac)$		$V_{REF} - 0.4$	1, 2, 3

1. The peak-to-peak AC component superimposed on V_{REF} may not exceed 5% of the DC component of V_{REF} .
2. Performance is a function of V_{IH} and V_{IL} levels to clock inputs.
3. See the *AC Input Definition* diagram.
4. See the *AC Input Definition* diagram. The signals should swing monotonically with no steps rail-to-rail with input signals never ringing back past $V_{IH} (AC)$ and $V_{IL} (AC)$ during the input setup and input hold window. $V_{IH} (AC)$ and $V_{IL} (AC)$ are used for timing purposes only.

Notes:

1. Q01 refers to the output from address A. Q02 refers to the output from the next internal burst address following A.
2. Outputs are disabled (high impedance) one clock cycle after a NOP.
3. The second NOP cycle is not necessary for correct device operation, however, at high clock frequencies, it might be required to prevent bus contention.

IEEE 1149.1 TAP and Boundary Scan

The SRAM provides a limited set of JTAG functions to test the interconnection between SRAM I/Os and printed circuit board traces or other components. There is no multiplexer in the path from I/O pins to the RAM core.

In conformance with IEEE Standard 1149.1, the SRAM contains a TAP controller, instruction register, boundary scan register, bypass register, and ID register.

The TAP controller has a standard 16-state machine that resets internally on power-up. Therefore, a TRST signal is not required.

Signal List

- TCK: test clock
- TMS: test mode select
- TDI: test data-in
- TDO: test data-out

111	BYPASS	Bypass Register	3

1. Places Qs in high-Z in order to sample all input data, regardless of other SRAM inputs.
2. TDI is sampled as an input to the first ID register to allow for the serial shift of the external TDI data.
3. BYPASS register is initiated to V_{SS} when BYPASS instruction is invoked. The BYPASS register also holds the last serially loaded TDI when exiting the shift-DR state.
4. SAMPLE instruction does not place DQs in high-Z.
5. This instruction is reserved. Invoking this instruction will cause improper SRAM functionality.
6. This EXTEST is not IEEE 1149.1-compliant. By default, it places Q in high-Z. If the internal register on the scan chain is set high, Q will be updated with information loaded via a previous SAMPLE instruction. The actual transfer occurs during the update IR state after EXTEST is loaded. The value of the internal register can be changed during SAMPLE and EXTEST only.

Компания «Life Electronics» занимается поставками электронных компонентов импортного и отечественного производства от производителей и со складов крупных дистрибьюторов Европы, Америки и Азии.

С конца 2013 года компания активно расширяет линейку поставок компонентов по направлению коаксиальный кабель, кварцевые генераторы и конденсаторы (керамические, пленочные, электролитические), за счёт заключения дистрибьюторских договоров

Мы предлагаем:

- Конкурентоспособные цены и скидки постоянным клиентам.
- Специальные условия для постоянных клиентов.
- Подбор аналогов.
- Поставку компонентов в любых объемах, удовлетворяющих вашим потребностям.
- Приемлемые сроки поставки, возможна ускоренная поставка.
- Доставку товара в любую точку России и стран СНГ.
- Комплексную поставку.
- Работу по проектам и поставку образцов.
- Формирование склада под заказчика.
- Сертификаты соответствия на поставляемую продукцию (по желанию клиента).
- Тестирование поставляемой продукции.
- Поставку компонентов, требующих военную и космическую приемку.
- Входной контроль качества.
- Наличие сертификата ISO.

В составе нашей компании организован Конструкторский отдел, призванный помогать разработчикам, и инженерам.

Конструкторский отдел помогает осуществить:

- Регистрацию проекта у производителя компонентов.
- Техническую поддержку проекта.
- Защиту от снятия компонента с производства.
- Оценку стоимости проекта по компонентам.
- Изготовление тестовой платы монтаж и пусконаладочные работы.
