<sup>1</sup>Measurement taken for single ended waveform on a component test board (not in system)

<sup>2</sup>Measurement taken from differential waveform on a component test board. (not in system)

<sup>3</sup>Slew rate emasured through V<sub>swing</sub> voltage range centered about differential zero

<sup>4</sup>V<sub>cross</sub> is defined at the voltage where Clock = Clock#, measured on a component test board (not in system)

<sup>5</sup>Only applies to the differential rising edge (Clock rising, Clock# falling)

<sup>6</sup>Matching applies to rising edge rate for Clock and falling edge rate for Clock#. It is measured using a +/-75mV window centered on the average cross point where Clock rising meets Clock# falling. The median cross point is used to calculate the voltage

<sup>7</sup>The max voltage including overshoot.

<sup>8</sup>The min voltage including undershoot.

<sup>9</sup>The total variation of all V<sub>cross</sub> measurements in any particular system. Note this is a subset of V<sub>cross</sub> min/mas (V<sub>Cross</sub> absolute) allowed. The intent is to limit V<sub>cross</sub> induced modulation by setting C<sub>cross\_delta</sub> to be smaller than V<sub>Cross</sub> absolute

<sup>1</sup>Jitter specs are specified as measured on a clock characterization board. System designers need to take special care not to use these numbers, as the in-system performance will be somewhat degraded. The receiver EMTS (chispet or CPU) will have the receiver jitter specs as measured in a real system.

<sup>2</sup>Phase jitter requirement: The designated Gen2 outputs will meet the reference clock jitter requirements from the PCI Express Gen2 Base Spec. The test is performed on a component test board under quiet conditions with all outputs on.

<sup>1</sup>Measurement taken for single ended waveform on a component test board (not in system)

<sup>2</sup>Measurement taken from differential waveform on a component test board. (not in system)

<sup>3</sup>Slew rate measured through minimum  $V_{swing}$  voltage range centered about differential zero

<sup>4</sup> $V_{cross}$  is defined at the voltage where Clock = Clock#, measured on a component test board (not in system)

<sup>5</sup>Only applies to the differential rising edge (Clock rising, Clock# falling)

<sup>6</sup>Matching applies to rising edge rate for Clock and falling edge rate for Clock#. It is measured using a +/-75mV window centered on the average cross point where Clock rising meets Clock# falling. The median cross point is used to calculate the voltage

<sup>7</sup>The max voltage including overshoot.

<sup>8</sup>The min voltage including undershoot.

<sup>9</sup>The total variation of all  $V_{cross}$  measurements in any particular system. Note this is a subset of  $V_{cross}$  min/max ( $V_{Cross}$  absolute) allowed. The intent is to limit  $V_{cross}$  induced modulation by setting  $C_{cross\_delta}$  to be smaller than  $V_{Cross}$  absolute

<sup>1</sup>Jitter specs are specified as measured on a clock characterization board. System designers need to take special care not to use these numbers, as the in-system performance will be somewhat degraded. The receiver EMTS (chispet or CPU) will have the receiver jitter specs as measured in a real system.

<sup>2</sup>Phase jitter requirement: The designated Gen2 outputs will meet the reference clock jitter requirements from the PCI Express Gen2 Base Spec. The test is performed on a component test board under quiet conditions with all outputs on.
