

2.5/3.3V 200-MHz High-Speed Multi-Phase PLL Clock Buffer

Features

- 2.5V or 3.3V operation
- Split output bank power supplies
- Output frequency range: 6 MHz to 200 MHz
- 45 ps typical cycle-cycle jitter
- $\pm 2\%$ max output duty cycle
- Selectable output drive strength
- Selectable positive or negative edge synchronization
- Eight LVTTTL outputs driving $50\ \Omega$ terminated lines
- LVCMOS/LVTTTL over-voltage tolerant reference input
- Selectable phase-locked loop (PLL) frequency range and lock indicator
- Phase adjustments in 625/1250 ps steps up to ± 7.5 ns
- (1-6, 8, 10, 12) x multiply and (1/2, 1/4) x divide ratios
- Spread-Spectrum compatible
- Power down mode
- Selectable reference divider
- Industrial temperature range: -40°C to $+85^{\circ}\text{C}$
- 44-pin TQFP package

Description

The CY7B995 RoboClock[®] is a low voltage, low power, eight-output, 200 MHz clock driver. It features output phase programmability which is necessary to optimize the timing of high performance computer and communication systems.

The user can program both the frequency and the phase of the output banks through nF[0:1] and DS[0:1] pins. The adjustable phase feature allows the user to skew the outputs to lead or lag the reference clock. Any one of the outputs can be connected to feedback to achieve different reference frequency multiplication, and divide ratios and zero input-output delay.

The device also features split output bank power supplies, which enable the user to run two banks (1Qn and 2Qn) at a power supply level, different from that of the other two banks (3Qn and 4Qn). The three-level PE/HD pin also controls the synchronization of the output signals to either the rising, or the falling edge of the reference clock and selects the drive strength of the output buffers. The high drive option (PE/HD = MID) increases the output current from ± 12 mA to ± 24 mA.

Pin	Name	IO ^[1]	Type	Description
39	REF	I	LVTTL/LVCMOS	Reference Clock Input.
17	FB	I	LVTTL	Feedback Input.
37	TEST	I	3-Level	When MID or HIGH, disables PLL^[3]. REF goes to all outputs. Set LOW for normal operation.
2	sOE#	I, PD	LVTTL	Synchronous Output Enable. When HIGH, it stops clock outputs (except 2Q0 and 2Q1) in a LOW state (for PE/HD = H or M) – 2Q0, and 2Q1 may be used as the feedback signal to maintain phase lock. When TEST is held at MID level and sOE# is HIGH, the nF[1:0] pins act as output disable controls for individual banks when nF[1:0] = LL. Set sOE# LOW for normal operation.
4	PE/HD	I, PU	3-Level	Selects Positive or Negative Edge Control, and High or Low output Drive Strength. When LOW/HIGH, the outputs are synchronized with the negative/positive edge of the reference clock respectively. When at MID level, the output drive strength is increased and the outputs synchronize with the positive edge of the reference clock. See Table 10 on page 5.
34, 33, 36, 35, 43, 42, 1, 44	nF[1:0]	I	3-Level	Selects Frequency and Phase of the Outputs. See Table 4 , Table 5 , Table 6 , Table 8 , and Table 9 on page 4.
41	FS	I	3-Level	Selects VCO Operating Frequency Range. See Table 7 on page 4.
26,27,20,21, 13,14,7,8	nQ[1:0]	O	LVTTL	Four banks of two outputs. See Table 6 on page 4 for frequency settings.
32, 31	DS[1:0]	I	3-Level	Selects Feedback Divider. See Table 3 on page 4.
3	PD#/DIV	I, PU	3-Level	Power down and Reference Divider Control. When LOW, shuts off entire chip. When at MID level, enables the reference divider. See Table 2 for settings.
30	LOCK	O	LVTTL	PLL Lock Indication Signal. HIGH indicates lock, LOW indicates the PLL is not locked, and outputs may not be synchronized to the input.
5,6	V _{DD} Q4 ^[2]	PWR	Power	Power supply for Bank 4 Output Buffers. See Table 11 on page 5 for supply level constraints.
15,16	V _{DD} Q3 ^[2]	PWR	Power	Power supply for Bank 3 Output Buffers. See Table 11 on page 5 for supply level constraints.
19,28,29	V _{DD} Q1 ^[2]	PWR	Power	Power supply for Bank 1 and Bank 2 Output Buffers. See Table 11 on page 5 for supply level constraints.
18,40	V _{DD} ^[2]	PWR	Power	Power supply for the Internal Circuitry. See Table 11 on page 5 for supply level constraints.

Device Configuration

The outputs of the CY7B995 can be configured to run at frequencies ranging from 6 MHz to 200 MHz. The feedback input divider is controlled by the 3-level DS[0:1] pins as indicated in [Table 3](#) on page 4, and the reference input divider is controlled by the 3-level PD#/DIV pin as indicated in [Table 2](#).

Table 2. Reference Divider Settings

PD#/DIV	R-Reference Divider
H	1
M	2
L ^[4]	N/A

Notes

1. PD indicates an internal pull down and 'PU' indicates an internal pull up.
2. A bypass capacitor (0.1μF) must be placed as close as possible to each positive power pin (< 0.2"). If these bypass capacitors are not close to the pins, their high frequency filtering characteristic is cancelled by the lead inductance of the traces.
3. When TEST = MID and sOE# = HIGH, PLL remains active with nF[1:0] = LL functioning as an output disable control for individual output banks. Skew selections remain in effect unless nF[1:0] = LL.
4. When PD#/DIV = LOW, the device enters power down mode.

In addition to the reference and feedback dividers, the CY7B995 includes output dividers on Bank3 and Bank4, which are controlled by 3F[1:0] and 4F[1:0] as indicated in Table 4 and Table 5, respectively.

The 3-level FS control pin setting determines the nominal operating frequency range of the divide-by-one outputs of the device. The CY7B995 PLL operating frequency range that corresponds to each FS level is given in Table 7.

Table 7. Frequency Range Select

FS	PLL Frequency Range
L	24 to 50 MHz
M	48 to 100 MHz
H	96 to 200 MHz

Selectable output skew is in discrete increments of time units (t_U). The value of t_U is determined by the FS setting and the maximum nominal frequency. The equation used to determine the t_U value is: $t_U = 1 / (f_{NOM} \times MF)$

where MF is a multiplication factor which is determined by the FS setting as indicated in Table 8.

Table 8. MF Calculation

FS	MF	f_{NOM} at which t_U is 1.0 ns (MHz)
L	32	31.25
M	16	62.5
H	8	125

Notes

- These states are used to program the phase of the respective banks. See Table 8 and Table 9.
- These outputs are undivided copies of the VCO clock. The formulas in this column can be used to calculate the VCO operating frequency (F_{NOM}) at a given reference frequency (F_{REF}), and divider and feedback configuration. The user must select a configuration and a reference frequency that generates a VCO frequency, and is within the range specified by FS pin. See Table 7.

In addition to determining whether the outputs synchronize to the rising or the falling edge of the reference signal, the 3-level PE/HD pin controls the output buffer drive strength as indicated in Table 10 on page 5. Refer to the AC Timing Definitions section for a description of input-to-output and output-to-output phase relationships.

The CY7B995 features split power supply buses for Banks 1 and 2, Bank 3 and Bank 4, which enables the user to obtain both 3.3V and 2.5V output signals from one device. The core power supply (V_{DD}) must be set at a level that is equal to or higher than any of the output power supplies.

Notes

- LL disables outputs if TEST = MID and SOE# = HIGH.
- When 4Q[0:1] are set to run inverted (HH mode), SOE# disables these outputs HIGH when PE/HD = HIGH or MID, SOE# disables them LOW when PE/HD = LOW.
- Please refer to "DC Parameters" section for I_{OH}/I_{OL} specifications.
- $V_{DDQ1/3/4}$ must not be set at a level higher than that of V_{DD} . They can be set at different levels from each other, e.g., $V_{DD} = 3.3V$, $V_{DDQ1} = 3.3V$, $V_{DDQ3} = 2.5V$ and $V_{DDQ4} = 2.5V$.

Notes

11. These Inputs are normally wired to VDD, GND or unconnected. Internal termination resistors bias unconnected inputs to V_{DD}/2.
12. IF PD#/DIV is in HIGH level (R-reference divider = 1). Reference Input Frequency = F_{REF}. IF PD#/DIV is in MID level (R-reference divider = 2). Reference Input Frequency = F_{REF} × 2.
13. Test Load = 20 pF, terminated to V_{CC}/2. All outputs are equally loaded.
14. t_{PD} is measured at 1.5V for V_{DD} = 3.3V and at 1.25V for V_{DD} = 2.5V with REF rise/fall times of 0.5 ns between 0.8V–2.0V.
15. t_{LOCK} is the time that is required before outputs synchronize to REF. This specification is valid with stable power supplies which are within normal operating limits.
16. Lock detector circuit may be unreliable for input frequencies lower than 4 MHz, or for input signals which contain significant jitter.

AC Timing Definitions

Figure 2. Timing Definition

With PE HIGH (LOW), the REF rising (falling) edges are aligned to the FB rising (falling) edges. Also, when PE is HIGH (LOW), all divided outputs' rising (falling) edges are aligned to the rising (falling) edges of the undivided, non-inverted outputs. Regardless of PE setting, divide-by-4 outputs' rising edges align to the divide-by-2 outputs' rising edges.

In cases where a non-divided output is connected to the FB input pin, the divided output rising edges can be either 0 or 180 degrees phase aligned to the REF input rising edges (as set randomly at power-up). If the divided outputs are required as rising-edge (falling-edge) aligned to the REF input's rising (falling) edge, set the PE pin HIGH (LOW) and connect the lowest frequency divided output to the FB input pin. This setup provides a consistent input-output and output-output phase relationship.
