

### FEATURES

Supports up to 40 MHz SPI clock speed in delay clock mode

Supports up to 17 MHz SPI clock speed in 4-wire mode

4 high speed, low propagation delay, SPI signal isolation channels

2 data channels at 250 kbps

Delayed compensation clock line

20-lead SOIC\_IC with 8.3 mm creepage

High temperature operation: 125°C

High common-mode transient immunity: >25 kV/μs

#### Safety and regulatory approvals

UL recognition per UL 1577

5000 V rms for 1 minute SOIC long package

CSA Component Acceptance Notice 5A

VDE certificate of conformity

DIN V VDE V 0884-10 (VDE V 0884-10):2006-12

V<sub>IORM</sub> = 849 V peak

### APPLICATIONS

Industrial programmable logic controllers (PLC)

Sensor isolation

### GENERAL DESCRIPTION

The ADuM4150<sup>1</sup> is a 6-channel, SPI Isolator™ digital isolator optimized for isolated serial peripheral interfaces (SPIs). Based on the Analog Devices, Inc., iCoupler® chip scale transformer technology, the low propagation delay in the CLK, MO/SI, MI/SO, and SS SPI bus signals supports SPI clock rates of up to 17 MHz. These channels operate with 13 ns propagation delay and 1 ns jitter to optimize timing for SPI.

The ADuM4150 isolator also provides two additional independent low data rate isolation channels, one channel in each direction. Data in the slow channels is sampled and serialized for a 250 kbps data rate with 2.5 μs of jitter.

The ADuM4150 supports a delay clock output on the master side of the device. This output can be used with an additional clocked port on the master to support 40 MHz clock performance. See the Delay Clock section for more information.

## SPECIFICATIONS

### ELECTRICAL CHARACTERISTICS—5 V OPERATION

All typical specifications are at  $T_A = 25^\circ\text{C}$  and  $V_{DD1} = V_{DD2} = 5\text{ V}$ . Minimum and maximum specifications apply over the entire recommended operation range:  $4.5\text{ V} \leq V_{DD1} \leq 5.5\text{ V}$ ,  $4.5\text{ V} \leq V_{DD2} \leq 5.5\text{ V}$ , and  $-40^\circ\text{C} \leq T_A \leq +125^\circ\text{C}$ , unless otherwise noted. Switching specifications are tested with  $C_L = 15\text{ pF}$  and CMOS signal levels, unless otherwise noted.

**Table 2. Switching Specifications**

Parameter	Symbol	A Grade			B Grade			Unit	Test Conditions/Comments
		Min	Typ	Max	Min	Typ	Max		
MCLK, MO, SO									
SPI Clock Rate	SPI <sub>MCLK</sub>			10			17	MHz	
Data Rate Fast (MO, SO)	DR <sub>FAST</sub>			40			40	Mbps	Within PWD limit
Propagation Delay	t <sub>PHL</sub> , t <sub>PLH</sub>			24	12		13	ns	50% input to 50% output
Pulse Width	PW	12.5			12.5			ns	Within PWD limit
Pulse Width Distortion	PWD			2			2	ns	t <sub>PLH</sub> - t <sub>PHL</sub>
Codirectional Channel Matching <sup>1</sup>	t <sub>PSKCD</sub>			2			2	ns	
Jitter, High Speed	J <sub>HS</sub>		1			1		ns	
MSS									
Data Rate Fast	DR <sub>FAST</sub>			40			40	Mbps	Within PWD limit
Propagation Delay	t <sub>PHL</sub> , t <sub>PLH</sub>		21	24		21	24	ns	50% input to 50% output
Pulse Width	PW	12.5			12.5			ns	Within PWD limit
Pulse Width Distortion	PWD			2			2	ns	t <sub>PLH</sub> - t <sub>PHL</sub>
Setup Time <sup>2</sup>	MSS <sub>SETUP</sub>	1.5			10			ns	
Jitter, High Speed	J <sub>HS</sub>		1			1		ns	
DCLK <sup>3</sup>									
Data Rate				40			40	MHz	
Propagation Delay	t <sub>PHL</sub> , t <sub>PLH</sub>			50			35	ns	t <sub>PMCLK</sub> + t <sub>PSO</sub> + 3 ns
Pulse Width Distortion	PWD			3			3	ns	t <sub>PLH</sub> - t <sub>PHL</sub>
Pulse Width	PW	12			12			ns	Within PWD limit
Clock Delay Error	DCLK <sub>ERR</sub>	0	4.5	12	1	5.5	12	ns	t <sub>PDCLK</sub> - (t <sub>PMCLK</sub> + t <sub>PSO</sub> )
Jitter	J <sub>DCLK</sub>		1			1		ns	
V <sub>IA</sub> , V <sub>IB</sub>									
Data Rate Slow	DR <sub>SLOW</sub>			250			250	kbps	Within PWD limit
Propagation Delay	t <sub>PHL</sub> , t <sub>PLH</sub>	0.1		2.6	0.1		2.6	μs	50% input to 50% output
Pulse Width	PW	4			4			μs	Within PWD limit
Jitter, Low Speed	J <sub>LS</sub>			2.5			2.5	μs	
V <sub>IX</sub> <sup>4</sup> Minimum Input Skew <sup>5</sup>	t <sub>VIX_SKEW</sub>	10			10			ns	

<sup>1</sup> Codirectional channel matching is the absolute value of the difference in propagation delays between any two channels with inputs on the same side of the isolation barrier.

<sup>2</sup> The MSS signal is glitch filtered in both speed grades, whereas the other fast signals are not glitch filtered in the B grade. To guarantee that MSS reaches the output ahead of another fast signal, set up MSS prior to the competing signal by different times depending on speed grade.

<sup>3</sup> t<sub>PMCLK</sub> is the propagation delay of the MCLK signal from Side 1 to Side 2. t<sub>PSO</sub> is the propagation delay of the SO signal from Side 2 to Side 1. t<sub>PDCLK</sub> is the difference between the DCLK signal and the round trip propagation delay.

<sup>4</sup> V<sub>IX</sub> = V<sub>IA</sub> or V<sub>IB</sub>.

<sup>5</sup> An internal asynchronous clock, not available to users, samples the low speed signals. If edge sequence in codirectional channels is critical to the end application, the leading pulse must be at least 1 t<sub>VIX\_SKEW</sub> time ahead of a later pulse to guarantee the correct order or simultaneous arrival at the output.

Quiescent Side 1 Current	I <sub>DD1(Q)</sub>		4.4		mA	
Quiescent Side 2 Current	I <sub>DD2(Q)</sub>		6.1		mA	
<b>AC SPECIFICATIONS</b>						
Output Rise/Fall Time	t <sub>R</sub> /t <sub>F</sub>		2.5		ns	10% to 90%
Common-Mode Transient Immunity <sup>4</sup>	CM	25	35		kV/μs	V <sub>INPUT</sub> = V <sub>DDx</sub> , V <sub>CM</sub> = 1000 V, transient magnitude = 800 V

<sup>1</sup> V<sub>DDx</sub> = V<sub>DD1</sub> or V<sub>DD2</sub>.<sup>2</sup> V<sub>INPUT</sub> is the input voltage of any of the MCLK, MSS, MO, SO, V<sub>IA</sub>, or V<sub>IB</sub> pins.<sup>3</sup> I<sub>OUTPUT</sub> is the output current of any of the SCLK, DCLK, SSS, MI, SI, V<sub>OA</sub>, or V<sub>OB</sub> pins.<sup>4</sup> |CM| is the maximum common-mode voltage slew rate that can be sustained while maintaining output voltages within the V<sub>OH</sub> and V<sub>OL</sub> limits. The common-mode voltage slew rates apply to both rising and falling common-mode voltage edges.

**ELECTRICAL CHARACTERISTICS—3.3 V OPERATION**

All typical specifications are at  $T_A = 25^\circ\text{C}$  and  $V_{DD1} = V_{DD2} = 3.3\text{ V}$ . Minimum and maximum specifications apply over the entire recommended operation range:  $3.0\text{ V} \leq V_{DD1} \leq 3.6\text{ V}$ ,  $3.0\text{ V} \leq V_{DD2} \leq 3.6\text{ V}$ , and  $-40^\circ\text{C} \leq T_A \leq +125^\circ\text{C}$ , unless otherwise noted. Switching specifications are tested with  $C_L = 15\text{ pF}$  and CMOS signal levels, unless otherwise noted.

**Table 4. Switching Specifications**

Parameter	Symbol	A Grade			B Grade			Unit	Test Conditions/Comments
		Min	Typ	Max	Min	Typ	Max

<sup>1</sup> V<sub>DDx</sub> = V<sub>DD1</sub> or V<sub>DD2</sub>.<sup>2</sup> V<sub>INPUT</sub> is the input voltage of any of the MCLK,  $\overline{\text{MSS}}$ , MO, SO, V<sub>IA</sub>, or V<sub>IB</sub> pins.<sup>3</sup> I<sub>OUTPUT</sub> is the output current of any of the SCLK, DCLK,  $\overline{\text{SSS}}$ , MI, SI, V<sub>OA</sub>, or V<sub>OB</sub> pins.<sup>4</sup> |CM| is the maximum common-mode voltage slew rate that can be sustained while maintaining output voltages within the V<sub>OH</sub> and V<sub>OL</sub> limits. The common-mode voltage slew rates apply to both rising and falling common-mode voltage edges.

**ELECTRICAL CHARACTERISTICS—MIXED 3.3 V/5 V OPERATION**

All typical specifications are at  $T_A = 25^\circ\text{C}$ ,  $V_{DD1} = 3.3\text{ V}$  and  $V_{DD2} = 5\text{ V}$ . Minimum and maximum specifications apply over the entire recommended operation range:  $3.0\text{ V} \leq V_{DD1} \leq 3.6\text{ V}$ ,  $4.5\text{ V} \leq V_{DD2} \leq 5.5\text{ V}$ , and  $-40^\circ\text{C} \leq T_A \leq +125^\circ\text{C}$ , unless otherwise noted. Switching specifications are tested with  $C_L = 15\text{ pF}$  and CMOS signal levels, unless otherwise noted.

**Table 8. Switching Specifications**

Parameter	Symbol	A Grade			B Grade			Unit	Test Conditions/Comments
		Min	Typ	Max	Min	Typ	Max		
MCLK, MO, SO									
SPI Clock Rate	$\text{SPI}_{\text{MCLK}}$			9.2			15.6	MHz	
Data Rate Fast (MO, SO)	$\text{DR}_{\text{FAST}}$			40			40	Mbps	Within PWD limit

Setup Time <sup>2</sup>	$\text{MSS}_{\text{SETUP}}$	1.5			10			ns	
Jitter, High Speed	$J_{\text{HS}}$		1			1		ns	
DCLK <sup>3</sup>									
Data Rate				40			40	MHz	
Propagation Delay	$t_{\text{PHL}}, t_{\text{PLH}}$			60			40	ns	$t_{\text{PMCLK}} + t_{\text{PSO}} + 3\text{ ns}$
Pulse Width Distortion	PWD			3			3	ns	$ t_{\text{PLH}} - t_{\text{PHL}} $
Pulse Width	PW	12			12			ns	Within PWD limit
Clock Delay Error	$\text{DCLK}_{\text{ERR}}$	2	7	13	2	6.8	11	ns	$t_{\text{PDCLK}} - (t_{\text{PMCLK}} + t_{\text{PSO}})$
Jitter	$J_{\text{DCLK}}$		1			1		ns	
$V_{\text{IA}}, V_{\text{IB}}$									
Data Rate Slow	$\text{DR}_{\text{SLOW}}$			250			250	kbps	Within PWD limit
Propagation Delay	$t_{\text{PHL}}, t_{\text{PLH}}$	0.1		2.6	0.1		2.6	$\mu\text{s}$	50% input to 50% output
Pulse Width	PW	4			4			$\mu\text{s}$	Within PWD limit
Jitter, Low Speed	$J_{\text{LS}}$			2.5			2.5	$\mu\text{s}$	
$V_{\text{IX}}$ <sup>4</sup> Minimum Input Skew <sup>5</sup>	$t_{\text{VIX\_SKEW}}$	10			10			ns	

<sup>1</sup> Codirectional channel matching is the absolute value of the difference in propagation delays between any two channels with inputs on the same side of the isolation barrier.

<sup>2</sup> The MSS signal is glitch filtered in both speed grades, whereas the other fast signals are not glitch filtered in the B grade. To guarantee that MSS reaches the output ahead of another fast signal, set up MSS prior to the competing signal by different times depending on speed grade.

<sup>3</sup>  $t_{\text{PMCLK}}$  is the propagation delay of the MCLK signal from Side 1 to Side 2.  $t_{\text{PSO}}$  is the propagation delay of the SO signal from Side 2 to Side 1.  $t_{\text{PDCLK}}$  is the difference between the DCLK signal and the round trip propagation delay.

<sup>4</sup>  $V_{\text{IX}} = V_{\text{IA}}$  or  $V_{\text{IB}}$ .

<sup>5</sup> An internal asynchronous clock, not available to users, samples the low speed signals. If edge sequence in codirectional channels is critical to the end application, the leading pulse must be at least 1  $t_{\text{VIX\_SKEW}}$  time ahead of a later pulse to guarantee the correct order or simultaneous arrival at the output.

<sup>1</sup> See the DC Correctness and Magnetic Field Immunity section for information on the immunity to external magnetic fields.

## ABSOLUTE MAXIMUM RATINGS

$T_A = 25^\circ\text{C}$ , unless otherwise noted.

Table 15.

Parameter	Rating <sup>1</sup>
Storage Temperature ( $T_{ST}$ ) Range	$-65^\circ\text{C}$ to $+150^\circ\text{C}$
Ambient Operating Temperature ( $T_A$ ) Range	$-40^\circ\text{C}$ to $+125^\circ\text{C}$
Supply Voltages ( $V_{DD1}$ , $V_{DD2}$ )	$-0.5\text{ V}$ to $+7.0\text{ V}$
Input Voltages ( $V_{IA}$ , $V_{IB}$ , MCLK, MO, SO, MSS)	$-0.5\text{ V}$ to $V_{DDx} + 0.5\text{ V}$
Output Voltages (SCLK, DCLK, $\overline{\text{SSS}}$ , MI, SI, $V_{OA}$ , $V_{OB}$ )	$-0.5\text{ V}$ to $V_{DDx} + 0.5\text{ V}$
Average Output Current per Pin <sup>2</sup>	$-10\text{ mA}$ to $+10\text{ mA}$
Common-Mode Transients <sup>3</sup>	$-100\text{ kV}/\mu\text{s}$ to $+100\text{ kV}/\mu\text{s}$

<sup>1</sup>  $V_{DDx} = V_{DD1}$  or  $V_{DD2}$ .

<sup>2</sup> See Figure 2 for maximum safety rated current values across temperature.

<sup>3</sup> Refers to common-mode transients across the insulation barrier. Common-mode transients exceeding the absolute maximum ratings may cause latch-up or permanent damage.

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

Table 16. Maximum Continuous Working Voltage<sup>1</sup>

Parameter	Value	Constraint
60 Hz AC Voltage	400 V rms	20 year lifetime at 0.1% failure rate, zero average voltage
DC Voltage	1173 V peak	Limited by the creepage of the package, Pollution Degree 2, Material Group II <sup>2,3</sup>

<sup>1</sup> See the Insulation Lifetime section for details.

<sup>2</sup> Other pollution degree and material group requirements yield a different limit.

<sup>3</sup> Some system level standards allow components to use the printed wiring board (PWB) creepage values. The supported dc voltage may be higher for those standards.

### ESD CAUTION

**ESD (electrostatic discharge) sensitive device.** Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

## PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

NOTES  
 1. NIC = NOT INTERNALLY CONNECTED. THIS PIN IS NOT INTERNALLY CONNECTED AND SERVES NO FUNCTION IN THE ADuM4150.

## APPLICATIONS INFORMATION

### INTRODUCTION

The ADuM4150 is part of a family of devices created to optimize isolation of SPI for speed and to provide additional low speed channels for control and status monitoring functions. The isolators are based on differential signaling *iCoupler* technology for enhanced speed and noise immunity.

#### High Speed Channels

The ADuM4150 has four high speed channels. The first three, CLK, MI/SO, and MO/SI (the slash indicates the connection of the particular input and output, forming a datapath across the isolator that corresponds to an SPI bus signal), are optimized for either low propagation delay in the B grade, or high noise immunity in the A grade. The difference between the grades is the addition of a glitch filter to these three channels in the A grade version, which increases propagation delay. The B grade version, with a maximum propagation delay of 13 ns, supports a maximum clock rate of 17 MHz in a standard 4-wire SPI. However, because the glitch filter is not present in the B grade version, ensure that spurious glitches of less than 10 ns are not present.

Glitches of less than 10 ns in the B grade devices can cause the second edge of the glitch to be missed. This pulse condition is seen as a spurious data transition on the output that is corrected by a refresh or the next valid data edge. It is recommended to use A grade devices in noisy environments.

The relationship between the SPI signal paths and the pin mnemonics of the ADuM4150 and data directions is summarized in Table 19.

**Table 19. Pin Mnemonic Correspondence to SPI Signal Path Names**

SPI Signal Path	Master Side 1	Data Direction	Slave Side 2
CLK	MCLK	→	SCLK
MO/SI	MO	→	SI
MI/SO	MI	←	SO
$\overline{SS}$	$\overline{MSS}$	→	$\overline{SSS}$

The datapaths are SPI mode agnostic. The CLK and MO/SI SPI datapaths are optimized for propagation delay and channel-to-channel matching. The MI/SO SPI datapath is optimized for propagation delay. The device does not synchronize to the clock channel, so there are no constraints on the clock polarity or the timing with respect to the data lines. To allow compatibility with nonstandard SPI interfaces, the MI pin is always active, and does not tristate when the slave select is not asserted. This precludes tying several MI lines together without adding a tristate buffer or multiplexor.

The  $\overline{SS}$  (slave select bar) is typically an active low signal. It can have many different functions in SPI and SPI like busses. Many of these functions are edge triggered; therefore, the  $\overline{SS}$  path contains a glitch filter in both the A grade and the B grade. The glitch filter prevents short pulses from propagating to the output or causing other errors in operation. The  $\overline{MSS}$  signal requires a 10 ns setup time in the B grade prior to the first active clock edge to allow the added propagation time of the glitch filter.

#### Low Speed Data Channels

The low speed data channels are provided as economical isolated datapaths where timing is not critical. The dc value of all high and low speed inputs on a given side of the device is sampled simultaneously, packetized, and shifted across an isolation coil. The high speed channels are compared for dc accuracy, and the low speed data is transferred to the appropriate low speed outputs. The process is then reversed by reading the inputs on the opposite side of the device, packetizing them, and sending them back for similar processing. The dc correctness data for the high speed channels is handled internally, and the low speed data is clocked to the outputs simultaneously.

This bidirectional data shuttling is regulated by a free running internal clock. Because data is sampled at discrete times based on this clock, the propagation delay for a low speed channel is between 0.1  $\mu$ s and 2.6  $\mu$ s depending on where the input data edge changes with respect to the internal sample clock.

Figure 10 illustrates the behavior of the low speed channels.

- Point A: The data may change as much as 2.6  $\mu$ s before it is sampled, then it takes about 0.1  $\mu$ s to propagate to the output. This difference appears as 2.5  $\mu$ s of uncertainty in the propagation delay time.
- Point B: Data pulses that are less than the minimum low speed pulse width may not be transmitted at all because they may not be sampled.

Figure 10. Low Speed Channel Timing

**Delay Clock**

The delay clock (DCLK) function allows SPI data transfers at speeds beyond the limitations usually set by propagation delay. The maximum speed of the clock in a 4-wire SPI application is set by the requirement that data shifts out on one clock edge and returning data shifts in on the complementary clock edge. In isolated systems, the delay through the isolator is significant. The first clock edge, telling the slave to present its data, must propagate through the isolator. The slave acts upon the clock edge, and data propagates back through the isolator to the master. The data must arrive back at the master before the complementary clock edge for the data to shift properly into the master.

For the example shown in Figure 11, if an isolator has a 50 ns propagation delay, it requires more than 100 ns for the response from the slave to arrive back at the master. This means that the fastest clock period for the SPI bus is 200 ns or 5 MHz, and assumes ideal conditions, such as no trace propagation delay or delay in the slave for simplicity.

Figure 11. Standard SPI Configuration

To avoid this limitation on the SPI clock, a second receive buffer can be used as shown in Figure 12, together with a clock signal that is delayed to match the data coming back from the slave. The proper delay of the clock was accomplished in the past by sending a copy of the clock back through a matching isolator channel and using the delayed clock to shift the slave data into a secondary buffer. Using an extra channel is costly because it consumes an additional high speed isolator channel.

Figure 12. High Speed SPI Using Isolation Channel Delay

The ADuM4150 eliminates the need for the extra high speed channel by implementing a delay circuit on the master side, as shown in Figure 13. DCLK is trimmed at the production test to match the round trip propagation delay of each isolator. The DCLK signal can be used as if the clock signal had propagated alongside the data from the slave in the scheme outlined previously.

Figure 13. High Speed SPI Using Precision Clock Delay

This configuration can operate at clock rates of up to 40 MHz. The MI/SO data is shifted into the secondary receive buffer by DCLK and then transferred internally by the master to its final destination. The ADuM4150 does not need to use an extra expensive isolator channel to achieve these data transfer speeds. Note that the  $\overline{SS}$  channel is not shown here for clarity.

**PRINTED CIRCUIT BOARD (PCB) LAYOUT**

The ADuM4150 digital isolator requires no external interface circuitry for the logic interfaces. Power supply bypassing is strongly recommended at both the  $V_{DD1}$  and  $V_{DD2}$  supply pins (see Figure 14). The capacitor value must be between 0.01  $\mu\text{F}$  and 0.1  $\mu\text{F}$ . The total lead length between both ends of the capacitor and the input power supply pin must not exceed 20 mm.

Figure 14. Recommended PCB Layout

In applications involving high common-mode transients, it is important to minimize board coupling across the isolation barrier. Furthermore, design the PCB layout so that any coupling that does occur equally affects all pins on a given component side. Failure to ensure this may cause voltage differentials between pins that exceed the absolute maximum ratings of the device, thereby leading to latch-up or permanent damage.

**PROPAGATION DELAY RELATED PARAMETERS**

Propagation delay is a parameter that describes the time it takes a logic signal to propagate through a component. The input-to-output propagation delay time for a high-to-low transition can differ from the propagation delay time of a low-to-high transition.

Figure 15. Propagation Delay Parameters

Pulse width distortion is the maximum difference between these two propagation delay values, and an indication of how accurately the timing of the input signal is preserved.

Channel-to-channel matching refers to the maximum amount that the propagation delay differs between channels within a single ADuM4150 component.

**DC CORRECTNESS AND MAGNETIC FIELD IMMUNITY**

Positive and negative logic transitions at the isolator input cause narrow (~1 ns) pulses to be sent via the transformer to the decoder. The decoder is bistable and is, therefore, either set or reset by the pulses indicating input logic transitions. In the absence of logic transitions at the input for more than ~1.2 μs, a periodic set of refresh pulses indicative of the correct input state are sent via the low speed channel to ensure dc correctness at the output.

If the low speed decoder receives no pulses for more than approximately 5 μs, the input side is assumed to be unpowered or nonfunctional, in which case, the isolator output is forced to a high-Z state by the watchdog timer circuit.

The limitation on the magnetic field immunity of the device is set by the condition in which the induced voltage in the transformer receiving coil is sufficiently large to either falsely set or reset the decoder. The following analysis defines such conditions. The ADuM4150 is examined in a 3 V operating condition because it represents the most susceptible mode of operation for this product.

The pulses at the transformer output have amplitudes greater than 1.5 V. The decoder has a sensing threshold of about 1.0 V, therefore establishing a 0.5 V margin in which induced voltages are tolerated. The voltage induced across the receiving coil is given by

$$V = (-d\beta/dt)\Sigma\pi r_n^2; n = 1, 2, \dots, N$$

where:

$\beta$  is the magnetic flux density.

$r_n$  is the radius of the  $n^{th}$  turn in the receiving coil.

$N$  is the number of turns in the receiving coil.

Given the geometry of the receiving coil in the ADuM4150 and an imposed requirement that the induced voltage be, at most, 50% of the 0.5 V margin at the decoder, a maximum allowable magnetic field is calculated as shown in Figure 16.

Figure 16. Maximum Allowable External Magnetic Flux Density

For example, at a magnetic field frequency of 1 MHz, the maximum allowable magnetic field of 0.5 kgauss induces a voltage of 0.25 V at the receiving coil. This voltage is about 50% of the sensing threshold and does not cause a faulty output transition. If such an event occurs, with the worst-case polarity, during a transmitted pulse, the interference reduces the received pulse from >1.0 V to 0.75 V. This voltage is still well above the 0.5 V sensing threshold of the decoder.

The preceding magnetic flux density values correspond to specific current magnitudes at given distances away from the ADuM4150 transformers. Figure 17 expresses these allowable current magnitudes as a function of frequency for selected distances. The ADuM4150 is very insensitive to external fields. Only extremely large, high frequency currents very close to the component may potentially be concerns. For the 1 MHz example noted, placing a 1.2 kA current 5 mm away from the ADuM4150 affects component operation.

Figure 17. Maximum Allowable Current for Various Current to ADuM4150 Spacings

Note that at combinations of strong magnetic field and high frequency, any loops formed by PCB traces may induce sufficiently large error voltages to trigger the thresholds of succeeding circuitry. Take care to avoid PCB structures that form loops.

## POWER CONSUMPTION

The supply current at a given channel of the ADuM4150 isolator is a function of the supply voltage, the data rate of the channel, and the output load of the channel and whether it is a high or low speed channel.

The low speed channels draw a constant quiescent current caused by the internal ping-pong datapath. The operating frequency is low enough that the capacitive losses caused by the recommended capacitive load are negligible compared to the quiescent current. The explicit calculation for the data rate is eliminated for simplicity, and the quiescent current for each side of the isolator attributable to the low speed channels can be found in Table 3, Table 5, Table 7, and Table 9 for the particular operating voltages. These quiescent currents add to the high speed current, as shown in the following equations, for the total current for each side of the isolator. Dynamic currents are from Table 3 and Table 5 for the respective voltages.

For Side 1, the supply current is given by

$$I_{DD1} = I_{DD1(D)} \times (f_{MCLK} + f_{MO} + f_{MSS}) + f_{MI} \times (I_{DDO(D)} + ((0.5 \times 10^{-3}) \times C_{L(MI)} \times V_{DD1})) + f_{MCLK} \times (I_{DDO(D)} + ((0.5 \times 10^{-3}) \times C_{L(DCLK)} \times V_{DD1})) + I_{DD1(Q)}$$

For Side 2, the supply current is given by

$$I_{DD2} = I_{DD1(D)} \times f_{SO} + f_{SCLK} \times (I_{DDO(D)} + ((0.5 \times 10^{-3}) \times C_{L(SCLK)} \times V_{DD2})) + f_{SI} \times (I_{DDO(D)} + ((0.5 \times 10^{-3}) \times C_{L(SI)} \times V_{DD2})) + f_{SSx} \times (I_{DDO(D)} + ((0.5 \times 10^{-3}) \times C_{L(SSx)} \times V_{DD2})) + I_{DD2(Q)}$$

where:

$I_{DD1(D)}$ ,  $I_{DDO(D)}$  are the input and output dynamic supply currents per channel (mA/Mbps).

$f_x$  is the logic signal data rate for the specified channel, expressed in units of Mbps.

$C_{L(x)}$  is the load capacitance of the specified output (pF).

$V_{DDx}$  is the supply voltage of the side being evaluated (V).

$I_{DD1(Q)}$ ,  $I_{DD2(Q)}$  are the specified Side 1 and Side 2 quiescent supply currents (mA).

Figure 4 and Figure 5 show the typical dynamic supply current per channel as a function of data rate for an input and unloaded output. Figure 6 and Figure 7 show the total  $I_{DD1}$  and  $I_{DD2}$  supply currents as a function of data rate for ADuM4150 channel configurations with all high speed channels running at the same speed and the low speed channels at idle.

## INSULATION LIFETIME

All insulation structures eventually break down when subjected to voltage stress over a sufficiently long period. The rate of insulation degradation is dependent on the characteristics of the voltage waveform applied across the insulation as well as on the materials and material interfaces.

Two types of insulation degradation are of primary interest: breakdown along surfaces exposed to the air and insulation wear out. Surface breakdown is the phenomenon of surface tracking and the primary determinant of surface creepage requirements in system level standards. Insulation wear out is the phenomenon where charge injection or displacement currents inside the insulation material cause long-term insulation degradation.

### Surface Tracking

Surface tracking is addressed in electrical safety standards by setting a minimum surface creepage based on the working voltage, the environmental conditions, and the properties of the insulation material. Safety agencies perform characterization testing on the surface insulation of components that allows the components to be categorized in different material groups. Lower material group ratings are more resistant to surface tracking and therefore can provide adequate lifetime with smaller creepage. The minimum creepage for a given working voltage and material group is in each system level standard and is based on the total rms voltage across the isolation, pollution degree, and material group. The material group and creepage for the ADuM4150 isolator is presented in Table 12.

### Insulation Wear Out

The lifetime of insulation caused by wear out is determined by its thickness, material properties, and the voltage stress applied. It is important to verify that the product lifetime is adequate at the application working voltage. The working voltage supported by an isolator for wear out may not be the same as the working voltage supported for tracking. It is the working voltage applicable to tracking that is specified in most standards.

Testing and modeling have shown that the primary driver of long-term degradation is displacement current in the polyimide insulation causing incremental damage. The stress on the insulation can be broken down into broad categories, such as: dc stress, which causes very little wear out because there is no displacement current, and an ac component time varying voltage stress, which causes wear out.

The ratings in certification documents are usually based on 60 Hz sinusoidal stress because this stress reflects isolation from line voltage. However, many practical applications have combinations of 60 Hz ac and dc across the barrier as shown in Equation 1. Because only the ac portion of the stress causes wear out, the equation can be rearranged to solve for the ac rms voltage, as is shown in Equation 2. For insulation wear out with the polyimide materials used in this product, the ac rms voltage determines the product lifetime.

$$V_{RMS} = \sqrt{V_{AC\ RMS}^2 + V_{DC}^2} \quad (1)$$

or

$$V_{AC\ RMS} = \sqrt{V_{RMS}^2 - V_{DC}^2} \quad (2)$$

where:

$V_{RMS}$  is the total rms working voltage.

$V_{AC\ RMS}$  is the time varying portion of the working voltage.

$V_{DC}$  is the dc offset of the working voltage.

#### Calculation and Use of Parameters Example

The following is an example that frequently arises in power conversion applications. Assume that the line voltage on one side of the isolation is 240 V ac rms and a 400 V dc bus voltage is present on the other side of the isolation barrier. The isolator material is polyimide. To establish the critical voltages in determining the creepage clearance and lifetime of a device, see Figure 18 and the following equations.

Figure 18. Critical Voltage Example

12371-01B

The working voltage across the barrier from Equation 1 is

$$V_{RMS} = \sqrt{V_{AC\ RMS}^2 + V_{DC}^2}$$

$$V_{RMS} = \sqrt{240^2 + 400^2}$$

$$V_{RMS} = 466\ \text{V rms}$$

This working voltage of 466 V rms is used together with the material group and pollution degree when looking up the creepage required by a system standard.

To determine if the lifetime is adequate, obtain the time varying portion of the working voltage. The ac rms voltage can be obtained from Equation 2.

$$V_{AC\ RMS} = \sqrt{V_{RMS}^2 - V_{DC}^2}$$

$$V_{AC\ RMS} = \sqrt{466^2 - 400^2}$$

$$V_{AC\ RMS} = 240\ \text{V rms}$$

In this case, ac rms voltage is simply the line voltage of 240 V rms. This calculation is more relevant when the waveform is not sinusoidal. The value is compared to the limits for working voltage in Table 16 for expected lifetime, less than a 60 Hz sine wave, and it is well within the limit for a 50 year service life.

Note that the dc working voltage limit in Table 16 is set by the creepage of the package as specified in IEC 60664-1. This value may differ for specific system level standards.

# OUTLINE DIMENSIONS

COMPLIANT TO JEDEC STANDARDS MS-013-AD

Figure 19. 20-Lead Standard Small Outline Package, with Increased Creepage [SOIC\_IC] Wide Body (RI-20-1)  
Dimension shown in millimeters

## ORDERING GUIDE

Model <sup>1,2</sup>	No. of Inputs, V <sub>DD1</sub> Side	No. of Inputs, V <sub>DD2</sub> Side	Maximum Data Rate (MHz)	Maximum Propagation Delay, 5 V (ns)	Isolation Rating (V ac)	Temperature Range	Package Description	Package Option
ADuM4150ARIZ	4	2	10	24	5000	-40°C to +125°C	20-Lead SOIC_IC	RI-20-1
ADuM4150ARIZ-RL	4	2	10	24	5000	-40°C to +125°C	20-Lead SOIC_IC, 13" Tape and Reel	RI-20-1
ADuM4150BRIZ	4	2	17	13	5000	-40°C to +125°C	20-Lead SOIC_IC	RI-20-1
ADuM4150BRIZ-RL	4	2	17	13	5000	-40°C to +125°C	20-Lead SOIC_IC, 13" Tape and Reel	RI-20-1
EVAL-ADuM3150Z							Evaluation Board	

<sup>1</sup> Z = RoHS Compliant Part.

<sup>2</sup> The EVAL-ADuM3150Z uses a functionally equivalent device for evaluation. The pad layout on the EVAL-ADuM3150Z evaluation board does not support the 20-lead SOIC\_IC package.

Компания «Life Electronics» занимается поставками электронных компонентов импортного и отечественного производства от производителей и со складов крупных дистрибьюторов Европы, Америки и Азии.

С конца 2013 года компания активно расширяет линейку поставок компонентов по направлению коаксиальный кабель, кварцевые генераторы и конденсаторы (керамические, пленочные, электролитические), за счёт заключения дистрибьюторских договоров

Мы предлагаем:

- Конкурентоспособные цены и скидки постоянным клиентам.
- Специальные условия для постоянных клиентов.
- Подбор аналогов.
- Поставку компонентов в любых объемах, удовлетворяющих вашим потребностям.
- Приемлемые сроки поставки, возможна ускоренная поставка.
- Доставку товара в любую точку России и стран СНГ.
- Комплексную поставку.
- Работу по проектам и поставку образцов.
- Формирование склада под заказчика.
- Сертификаты соответствия на поставляемую продукцию (по желанию клиента).
- Тестирование поставляемой продукции.
- Поставку компонентов, требующих военную и космическую приемку.
- Входной контроль качества.
- Наличие сертификата ISO.

В составе нашей компании организован Конструкторский отдел, призванный помогать разработчикам, и инженерам.

Конструкторский отдел помогает осуществить:

- Регистрацию проекта у производителя компонентов.
- Техническую поддержку проекта.
- Защиту от снятия компонента с производства.
- Оценку стоимости проекта по компонентам.
- Изготовление тестовой платы монтаж и пусконаладочные работы.
