

Description

The 9ZXL1530D / 9ZXL1550D are second-generation enhanced-performance DB1900Z-derivative differential buffers. The parts are pin-compatible upgrades to the 9ZXL1530B and 9ZXL1550B, while offering a much improved phase jitter performance. A fixed external feedback maintains low drift for critical QPI/UPI applications. In fanout mode, the devices meet the DB2000Q additive phase jitter specification.

Absolute Maximum Ratings

Stresses above the ratings listed below can cause permanent damage to the 9ZXL1530D / 9ZXL1550D. These ratings, which are standard values for IDT commercially rated parts, are stress ratings only. Functional operation of the device at these or any other conditions above those indicated in the operational sections of the specifications is not implied. ¹ Measured into fixed 2pF load cap. Input to output skew is measured at the first output edge following the corresponding input.

² Measured from differential cross-point to differential cross-point. This parameter can be tuned with external feedback path, if present.

³ All Bypass Mode input-to-output specs refer to the timing between an input edge and the specific output edge created by it.

⁴ This parameter is deterministic for a given device.

⁵ Measured with scope averaging on to find mean value.

⁶ "t" is the period of the input clock.

⁷ Measured as maximum pass band gain. At frequencies within the loop BW, highest point of magnification is called PLL jitter peaking.

⁸ Guaranteed by design and characterization, not 100% tested in production.

⁹ Measured at 3db down or half power point.

¹⁰ Duty cycle distortion is the difference in duty cycle between the output and the input clock when the device is operated in Bypass Mode.

¹¹ Measured from differential waveform.

Crossing Voltage (var)	Δ -Vcross	Scope averaging off.		24	63	140	mV	1,6,7

¹ Guaranteed by design and characterization, not 100% tested in production.

² Measured from differential waveform.

³ Slew rate is measured through the Vswing voltage range centered around differential 0V. This results in a \pm 150mV window around differential 0V.

⁴ Matching applies to rising edge rate for Clock and falling edge rate for Clock#. It is measured using a \pm 75mV window centered on the average cross point where Clock rising meets Clock# falling. The median cross point is used to calculate the voltage thresholds the oscilloscope is to use for the edge rate calculations.

⁵ Vcross is defined as voltage where Clock = Clock# measured on a component test board and only applies to the differential rising edge (i.e. Clock rising and Clock# falling).

⁶ The total variation of all Vcross measurements in any particular system. Note that this is a subset of Vcross_min/max (Vcross absolute) allowed. The intent is to limit Vcross induced modulation by setting Δ -Vcross to be smaller than Vcross absolute.

⁷ At default SMBus settings.

Notes for PCIe Filtered Phase Jitter tables (CC) and (IR).

- ¹ Applies to all differential outputs, guaranteed by design and characterization.
- ² Calculated from Intel™-supplied clock jitter tool when driven by 9SQL495x or equivalent with spread on and off.
- ³ Sample size of at least 100K cycles. This figure extrapolates to 108ps pk-pk at 1M cycles for a BER of 1^{-12} .
- ⁴ For RMS values, additive jitter is calculated by solving for b [$b = \sqrt{c^2 - a^2}$] where “a” is rms input jitter and “c” is rms total jitter.
- ⁵ IR is the new name for Separate Reference Independent Spread (SRIS) and Separate Reference no Spread (SRNS) PCIe clock architectures. According to the PCIe Base Specification Rev4.0 version 0.7 draft, the jitter transfer functions and corresponding jitter limits are not defined for the IR clock architecture. Widely accepted industry limits using widely accepted industry filters are used to populate this table. There are no accepted filters or limits for IR clock architectures at PCIe Gen1 or Gen4 data rates.
