

Is Now Part of

ON Semiconductor®

To learn more about ON Semiconductor, please visit our website at
www.onsemi.com

Please note: As part of the Fairchild Semiconductor integration, some of the Fairchild orderable part numbers will need to change in order to meet ON Semiconductor's system requirements. Since the ON Semiconductor product management systems do not have the ability to manage part nomenclature that utilizes an underscore (_), the underscore (_) in the Fairchild part numbers will be changed to a dash (-). This document may contain device numbers with an underscore (_). Please check the ON Semiconductor website to verify the updated device numbers. The most current and up-to-date ordering information can be found at www.onsemi.com. Please email any questions regarding the system integration to Fairchild_questions@onsemi.com.

FAN4800AS/CS/01S/2S PFC/PWM Controller Combination

Features

- Pin-to-Pin Compatible with ML4800 and FAN4800 and CM6800 and CM6800A
- PWM Configurable for Current Mode or Feedforward Voltage-Mode Operation
- Internally Synchronized Leading-Edge PFC and Trailing-Edge PWM in One IC
- Low Operating Current
- Innovative Switching-Charge Multiplier Divider
- Average-Current Mode for Input-Current Shaping
- PFC Over-Voltage and Under-Voltage Protections
- PFC Feedback Open-Loop Protection
- Cycle-by-Cycle Current Limiting for PFC/PWM
- Power-on Sequence Control and Soft-Start
- Brownout Protection
- Interleaved PFC/PWM Switching
- Improved Efficiency at Light Load
- $f_{RTCT}=4 \cdot f_{PFC}=4 \cdot f_{PWM}$ for FAN4800AS/01S
- $f_{RTCT}=4 \cdot f_{PFC}=2 \cdot f_{PWM}$ for FAN4800CS/02S

Applications

- Desktop PC Power Supply
- Internet Server Power Supply
- LCD TV, Monitor Power Supply
- UPS
- Battery Charger
- DC Motor Power Supply
- Monitor Power Supply
- Telecom System Power Supply
- Distributed Power

- [AN-8027 - FAN480X PFC+PWM Combination Controller Application](#)

Description

The highly integrated FAN4800AS/CS/01S/02S parts are specially designed for power supplies that consist of boost PFC and PWM. They require very few external components to achieve versatile protections / compensation. They are available in 16-pin DIP and SOP packages.

The PWM can be used in either current or voltage mode. In voltage mode, feed-forward from the PFC output bus can reduce the secondary output ripple.

Compared with older productions, ML4800 and FAN4800, FAN4800AS/CS/01S/02S have lower operation current that saves power consumption in external devices. FAN4800AS/CS/01S/02S have accurate 49.9% maximum duty of PWM that makes the hold-up time longer. Brownout protection and PFC soft-start functions available in this series are not available in ML4800 and FAN4800.

To evaluate FAN4800AS/CS/01S/02S for replacing existing FAN4800 and ML4800 boards, five things must be completed before the fine-tuning procedure:

1. Change R_{AC} resistor from the old value to a higher resistor: between 6 M Ω to 8 M Ω .
2. Change RT/CT pin from the existing values to $R_T=6.8k\Omega$ and $C_T=1000$ pF to have $f_{PFC}=64$ kHz and $f_{PWM}=64$ kHz.
3. The VRMS pin needs to be 1.224 V at $V_{IN}=85 V_{AC}$ for universal input application from line input from 85 V_{AC} to 270 V_{AC} .
4. At full load, the average V_{VEA} needs to be ~ 4.5 V and the ripple of V_{VEA} needs to be less than 400 mV.
5. For the Soft-Start pin, the soft-start current has been reduced to half the FAN4800 capacitor.

There are two differences from FAN4800A/C/01/02 to FAN4800AS/CS/01S/02S:

1. Under-voltage protection debounce time is extended to one second.
2. PWM gate clamp voltage is raised to 19 V.

Ordering Information

| Part Number | Operating Temperature Range | Package | Packing Method |
|-------------|-----------------------------|------------------------------------|----------------|
| FAN4800ASNY | -40°C to +105°C | 16-Pin Dual Inline Package (DIP) | Tube |
| FAN4800ASMY | -40°C to +105°C | 16-Pin Small Outline Package (SOP) | Tape & Reel |
| FAN4800CSNY | -40°C to +105°C | 16-Pin Dual Inline Package (DIP) | Tube |
| FAN4800CSMY | -40°C to +105°C | 16-Pin Small Outline Package (SOP) | Tape & Reel |
| FAN4801SNY | -40°C to +105°C | 16-Pin Dual Inline Package (DIP) | Tube |
| FAN4801SMY | -40°C to +105°C | 16-Pin Small Outline Package (SOP) | Tape & Reel |
| FAN4802SNY | -40°C to +105°C | 16-Pin Dual Inline Package (DIP) | Tube |
| FAN4802SMY | -40°C to +105°C | 16-Pin Small Outline Package (SOP) | Tape & Reel |

Pin Configuration

Figure 7. Pin Configuration (Top View)

Pin Definitions

| Pin # | Name | Description |
|-------|--------|---|
| 1 | IEA | Output of PFC Current Amplifier. The signal from this pin is compared with an internal sawtooth to determine the pulse width for PFC gate drive. |
| 2 | IAC | Input AC Current. For normal operation, this input provides current reference for the multiplier. The suggested maximum IAC is 100 μ A. |
| 3 | ISENSE | PFC Current Sense. The non-inverting input of the PFC current amplifier and the output of multiplier and PFC ILIMIT comparator. |
| 4 | VRMS | Line-Voltage Detection. The pin is used for the PFC multiplier. |
| 5 | SS | PWM Soft-Start. During startup, the SS pin charges an external capacitor with a 10 μ A constant current source. The voltage on FBPWM is clamped by SS during startup. If a protection condition occurs and/or PWM is disabled, the SS pin is quickly discharged. |
| 6 | FBPWM | PWM Feedback Input. The control input for voltage-loop feedback of PWM stage. |
| 7 | RT/CT | Oscillator RC Timing Connection. Oscillator timing node; timing set by R_T and C_T . |
| 8 | RAMP | PWM RAMP Input. In current mode, this pin functions as the current-sense input; when in voltage mode, it is the feedforward sense input from PFC output 380 V (feedforward ramp). |
| 9 | ILIMIT | Peak Current Limit Setting for PWM. The peak current limits setting for PWM. |
| 10 | GND | Ground. |
| 11 | OPWM | PWM Gate Drive. The totem-pole output drive for PWM MOSFET. This pin is internally clamped under 19 V to protect the MOSFET. |
| 12 | OPFC | PFC Gate Drive. The totem-pole output drive for PFC MOSFET. This pin is internally clamped under 15 V to protect the MOSFET. |
| 13 | VDD | Supply. The power supply pin. The threshold voltages for startup and turn-off are 11 V and 9.3 V, respectively. The operating current is lower than 10 mA. |
| 14 | VREF | Reference Voltage. Buffered output for the internal 7.5 V reference. |
| 15 | FBPFC | Voltage Feedback Input for PFC. The feedback input for PFC voltage loop. The inverting input of PFC error amplifier. This pin is connected to the PFC output through a divider network. |
| 16 | VEA | Output of PFC Voltage Amplifier. The error amplifier output for PFC voltage feedback loop. A compensation network is connected between this pin and ground. |

Absolute Maximum Ratings

Stresses exceeding the absolute maximum ratings may damage the device. The device may not function or be operable above the recommended operating conditions and stressing the parts to these levels is not recommended. In addition, extended exposure to stresses above the recommended operating conditions may affect device reliability. The absolute maximum ratings are stress ratings only.

| Symbol | Parameter | Min. | Max. | Unit |
|---------------|--|----------------------|----------------|--------------------|
| V_{DD} | DC Supply Voltage | | 30 | V |
| V_H | SS, FBPWM, RAMP, OPWM, OPFC, VREF | -0.3 | 30.0 | V |
| V_L | IAC, VRMS, RT/CT, ILIMIT, FBPFC, VEA | -0.3 | 7.0 | V |
| V_{IEA} | IEA | 0 | $V_{VREF}+0.3$ | V |
| V_N | ISENSE | -5.0 | 0.7 | V |
| I_{AC} | Input AC Current | | 1 | mA |
| I_{REF} | V_{REF} Output Current | | 5 | mA |
| $I_{PFC-OUT}$ | Peak PFC OUT Current, Source or Sink | | 0.5 | A |
| $I_{PWM-OUT}$ | Peak PWM OUT Current, Source or Sink | | 0.5 | A |
| P_D | Power Dissipation $T_A < 50^\circ\text{C}$ | | 800 | mW |
| Θ_{JA} | Thermal Resistance (Junction-to-Air) | DIP | 80.80 | $^\circ\text{C/W}$ |
| | | SOP | 104.10 | |
| Θ_{JC} | Thermal Resistance (Junction-to-Case) | DIP | 35.38 | $^\circ\text{C/W}$ |
| | | SOP | 40.41 | |
| T_J | Operating Junction Temperature | -40 | +125 | $^\circ\text{C}$ |
| T_{STG} | Storage Temperature Range | -55 | +150 | $^\circ\text{C}$ |
| T_L | Lead Temperature(Soldering) | | +260 | $^\circ\text{C}$ |
| ESD | Electrostatic Discharge Capability | Human Body Model | 5.0 | kV |
| | | Charged Device Model | 1.5 | |

Notes:

1. All voltage values, except differential voltage, are given with respect to GND pin.
2. Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device.

Recommended Operating Conditions

The Recommended Operating Conditions table defines the conditions for actual device operation. Recommended operating conditions are specified to ensure optimal performance to the datasheet specifications. Fairchild does not recommend exceeding them or designing to Absolute Maximum Ratings.

| Symbol | Parameter | Min. | Typ. | Max. | Unit |
|--------|-------------------------------|------|------|------|------------------|
| T_A | Operating Ambient Temperature | -40 | | +105 | $^\circ\text{C}$ |

Electrical Characteristics

Unless otherwise noted, $V_{DD}=15\text{ V}$, $T_A=25^\circ\text{C}$, $T_A=T_J$, $R_T=6.8\text{ k}\Omega$, and $C_T=1000\text{ pF}$.

Functional Description

The FAN4800AS/CS/01S/02S consist of an average current controlled, continuous-boost, Power Factor Correction (PFC) front-end and a synchronized Pulse Width Modulator (PWM) back-end. The PWM can be used in current or voltage mode. In voltage mode, feedforward from the PFC output bus can help improve the line regulation of PWM. In either mode, the PWM stage uses conventional trailing-edge, duty-cycle modulation. This proprietary leading / trailing edge modulation results in a higher usable PFC error amplifier bandwidth and can significantly reduce the size of the PFC DC bus capacitor.

The synchronization of the PWM with the PFC simplifies the PWM compensation due to the controlled ripple on the PFC output capacitor (the PWM input capacitor).

In addition to power factor correction, a number of protection features are built into this series. They include soft-start, PFC over-voltage protection, peak current limiting, brownout protection, duty cycle limiting, and under-voltage lockout (UVLO).

Gain Modulator

The gain modulator is the heart of the PFC, as the circuit block controls the response of the current loop to line voltage waveform and frequency, RMS line voltage, and PFC output voltages. There are three inputs to the gain modulator:

1. A current representing the instantaneous input voltage (amplitude and wave shape) to the PFC. The rectified AC input sine wave is converted to a proportional current via a resistor and is fed into the gain modulator at IAC. Sampling current in this way minimizes ground noise, required in high-power, switching-power conversion environments. The gain modulator responds linearly to this current.
2. A voltage proportional to the long-term RMS AC line voltage, derived from the rectified line voltage after scaling and filtering. This signal is presented to the gain modulator at VRMS. The output of the gain modulator is inversely proportional to V_{RMS} (except at unusually low values of V_{RMS} , where special gain contouring takes over to limit power dissipation of the circuit components under brownout conditions).
3. The output of the voltage error amplifier, V_{EA} . The gain modulator responds linearly to variations in V_{VEA} .

The output of the gain modulator is a current signal, in the form of a full wave rectified sinusoid at twice the line frequency. This current is applied to the virtual ground (negative) input of the current error amplifier. In this way, the gain modulator forms the reference for the current error loop and ultimately controls the instantaneous current draw of the PFC from the power line. The general form of the output of the gain modulator is:

$$I_{GAINMOD} = \frac{I_{AC} \times (V_{EA} - 0.7)}{VRMS^2} \times K \quad (1)$$

Note that the output current of the gain modulator is limited around 159 μA and the maximum output voltage of the gain modulator is limited to 159 $\mu A \times 5.7 k = 0.906 V$. This 0.906 V also determines the maximum input power. However, $I_{GAINMOD}$ cannot be measured directly from ISENSE. $I_{SENSE} = I_{GAINMOD} - I_{OFFSET}$ and I_{OFFSET} can only be measured when V_{VEA} is less than 0.5 V and $I_{GAINMOD}$ is 0 A. Typical I_{OFFSET} is around 31 $\mu A \sim 48 \mu A$.

Selecting R_{AC} for the IAC Pin

The IAC pin is the input of the gain modulator and also a current mirror input that requires current input. Selecting a proper resistor, R_{AC} , provides a good sine wave current derived from the line voltage and helps program the maximum input power and minimum input line voltage. $R_{AC} = V_{IN \text{ peak}} \times 56 k\Omega$. For example, if the minimum line voltage is 75 V_{AC}, the $R_{AC} = 75 \times 1.414 \times 56 k\Omega = 6 M\Omega$.

Current Amplifier Error, IEA

The current error amplifier's output controls the PFC duty cycle to keep the average current through the boost inductor a linear function of the line voltage. At the inverting input to the current error amplifier, the output current of the gain modulator is summed with a current, which results in a negative voltage being impressed upon the ISENSE pin.

The negative voltage on ISENSE represents the sum of all currents flowing in the PFC circuit and is typically derived from a current-sense resistor in series with the negative terminal of the input bridge rectifier.

The inverting input of the current error amplifier is a virtual ground. Given this fact, and the arrangement of the duty cycle modulator polarities internal to the PFC, an increase in positive current from the gain modulator causes the output stage to increase its duty cycle until the voltage on ISENSE is adequately negative to cancel this increased current. Similarly, if the gain modulator's output decreases, the output duty cycle decreases to achieve a less negative voltage on the ISENSE pin.

PFC Cycle-By-Cycle Current Limiter

In addition to being a part of the current feedback loop, the ISENSE pin is a direct input to the cycle-by-cycle current limiter for the PFC section. If the input voltage at this pin is less than -1.15 V, the output of the PFC is disabled until the protection flip-flop is reset by the clock pulse at the start of the next PFC power cycle.

TriFault Detect™

To improve power supply reliability, reduce system component count, and simplify compliance to UL1950 safety standards; the FAN4800AS/CS/01S/02S includes TriFault Detect™ technology. This feature monitors FBPF for certain PFC fault conditions.

In a feedback path failure, the output of the PFC could exceed safe operating limits. With such a failure, FBPF exceeds its normal operating area. Should FBPF go too low, too high, or open; TriFault Detect™ senses the error and terminates the PFC output drive.

TriFault Detect is an entirely internal circuit. It requires no external components to serve its protective function.

PFC Over-Voltage Protection

In the FAN4800AS/CS/01S/02S, the PFC OVP comparator serves to protect the power circuit from being subjected to excessive voltages if the load changes suddenly. A resistor divider from the high-voltage DC output of the PFC is fed to FBPF. When the voltage on FBPF exceeds 2.75 V, the PFC output driver is shut down. The PWM section continues to operate. The OVP comparator has 250 mV of hysteresis and the PFC does not restart until the voltage at FBPF drops below 2.5 V. V_{DD} OVP can also serve as a redundant PFC OVP protection. V_{DD} OVP threshold is 28 V with 1 V hysteresis.

Selecting PFC R_{sense}

R_{sense} is the sensing resistor of the PFC boost converter. During the steady state, line input current $\times R_{sense}$ equals $I_{GAINMOD} \times 5.7$ k Ω .

At full load, the average V_{VEA} needs to be around 4.5 V and ripple on the VEA pin needs to be less than 400 mV. Choose the resistance of the sensing resistor:

$$R_{SENSE} = \frac{(4.5 - 0.7) \times 5.7 \text{ k}\Omega \times I_{AC} \times \text{Gain} \times V_{IN} \times \sqrt{2}}{2 \times (5.6 - 0.7) \times \text{Line_Input_Power}} \quad (2)$$

where 5.6 is V_{VEA} maximum output voltage.

PFC Soft-Start

PFC startup is controlled by V_{VEA} level. Before the FBPF voltage reaches 2.4 V, the V_{VEA} level is around 2.8 V. At 90 V_{AC} , the PFC soft-start time is 90 ms.

PFC Brownout

The AC UVP comparator monitors the AC input voltage. The PFC is disabled as AC input lowers, causing V_{RMS} to be less than 1.05 V.

Error Amplifier Compensation

The PWM loading of the PFC can be modeled as a negative resistor because an increase in the input voltage to the PWM causes a decrease in the input current. This response dictates the proper compensation of the two transconductance error amplifiers. Figure 26 shows the types of compensation networks most commonly used for the voltage and current error amplifiers, along with their respective return points. The current-loop compensation is returned to V_{REF} to produce a soft-start characteristic on the PFC. As the reference voltage increases from 0V, it creates a differentiated voltage on IEA, which prevents the PFC from immediately demanding a full duty cycle on its boost converter. Complete design is discussed in application note AN-6078SC.

There is an RC filter between R_{sense} and ISENSE pin. There are two reasons to add a filter at the ISENSE pin:

1. Protection: During startup or inrush current conditions, there is a large voltage across R_{sense} , the sensing resistor of the PFC boost converter. It requires the I_{SENSE} filter to attenuate the energy.
2. To reduce inductance, L, the boost inductor. The I_{SENSE} filter also can reduce the boost inductor value since the I_{SENSE} filter behaves like an integrator before the ISENSE pin, which is the input of the current error amplifier, IEA.

The I_{SENSE} filter is an RC filter. The resistor value of the I_{SENSE} filter is between 100 Ω and 50 Ω because $I_{OFFSET} \times R_{FILTER}$ can generate a negative offset voltage of IEA. Selecting an R_{FILTER} equal to 50 Ω keeps the offset of the IEA less than 3 mV. Design the pole of the I_{SENSE} filter at $f_{PFC}/6$, one sixth of the PFC switching frequency, so the boost inductor can be reduced six times without disturbing the stability. The capacitor of the I_{SENSE} filter, C_{FILTER} , is approximately 100 nF.

Figure 26. Compensation Network Connection for the Voltage and Current Error Amplifiers

Two-Level PFC Function

To improve the efficiency, the system can reduce PFC switching loss at low line and light load by reducing the PFC output voltage. The two-level PFC output of the FAN4801S/02S can be programmable.

As Figure 27 shows, FAN4801S/02S detect the voltage of VEA and VRMS pins to determine if the system operates low line and light load. At the second-level PFC, there is a current of 20 μ A through R_{F2} from the FBPF pin. The second-level PFC output voltage can be calculated as.

$$\text{Output} \approx \frac{R_{F1} + R_{F2}}{R_{F2}} \times (2.5V - 20\mu A \times R_{F2}) \quad (3)$$

For example, if the second-level PFC output voltage is expected as 300 V and normal voltage is 387 V, according to the equation, R_{F2} is 28 k Ω R_{F1} is 4.3 M Ω .

The programmable range of second level PFC output voltage is 340 V ~ 300 V.

Figure 27. Two-Level PFC Scheme

Oscillator (RT/CT)

The oscillator frequency is determined by the values of R_T and C_T , which determine the ramp and off-time of the oscillator output clock:

$$f_{RT/CT} = \frac{1}{t_{RT/CT} + t_{DEAD}} \quad (4)$$

The dead time of the oscillator is derived from the following equation:

$$t_{RT/CT} = C_T \times R_T \times \ln\left(\frac{V_{REF} - 1}{V_{REF} - 3.8}\right) \quad (5)$$

at $V_{REF}=7.5$ V and $t_{RT/CT}=C_T \times R_T \times 0.56$.

The dead time of the oscillator is determined using:

$$t_{DEAD} = \frac{2.8V}{7.78mA} \times C_T = 360 \times C_T \quad (6)$$

The dead time is so small ($t_{RT/CT} \gg t_{DEAD}$) that the operating frequency can typically be approximated by:

$$f_{RT/CT} = \frac{1}{t_{RT/CT}} \quad (7)$$

Pulse Width Modulator (PWM)

The operation of the PWM section is straightforward, but there are several points that should be noted. Foremost among these is the inherent synchronization of PWM with the PFC section of the device, from which it also derives its basic timing. The PWM is capable of current-mode or voltage-mode operation. In current-mode applications, the PWM ramp (RAMP) is usually derived directly from a current-sensing resistor or current transformer in the primary side of the output stage. It is thereby representative of the current flowing in the converter's output stage. I_{LIMIT} , which provides cycle-by-cycle current limiting, is typically connected to RAMP in such applications. For voltage-mode operation and certain specialized applications, RAMP can be connected to a separate RC timing network to generate a voltage ramp against which FBPWM is compared. Under these conditions, the use of voltage feedforward from the PFC bus can assist in line regulation accuracy and response. As in current-mode operation, the I_{LIMIT} input is used for output stage over-current protection. No voltage error amplifier is included in the PWM stage, as this function is generally performed on the output side of the PWM's isolation boundary. To facilitate the design of opto-coupler feedback circuitry, an offset has been built into the PWM's RAMP input that allows FBPWM to command a 0% duty cycle for input voltages below typical 1.5 V.

PWM Cycle-by-Cycle Current Limiter

The I_{LIMIT} pin is a direct input to the cycle-by-cycle current limiter for the PWM section. Should the input voltage at this pin exceed 1 V, the output flip-flop is reset by the clock pulse at the start of the next PWM power cycle. When the I_{LIMIT} triggers the cycle-by-cycle bi-cycle current, it limits the PWM duty cycle mode and the power dissipation is reduced during the dead-short condition.

V_{IN} OK Comparator

The V_{IN} OK comparator monitors the DC output of the PFC and inhibits the PWM if the voltage on FBPF is less than its nominal 2.4 V. Once the voltage reaches 2.4 V, which corresponds to the PFC output capacitor being charged to its rated boost voltage, soft-start begins.

PWM Soft-Start (SS)

PWM startup is controlled by selection of the external capacitor at soft-start. A current source of 10 μ A supplies the charging current for the capacitor and startup of the PWM begins at 1.5 V.

PWM Control (RAMP)

When the PWM section is used in current mode, RAMP is generally used as the sampling point for a voltage, representing the current in the primary of the PWM's output transformer. The voltage is derived either from a current-sensing resistor or a current transformer. In voltage mode, RAMP is the input for a ramp voltage generated by a second set of timing components (R_{RAMP} , C_{RAMP}) that have a minimum value of 0V and a peak value of approximately 6V. In voltage mode, feedforward from the PFC output bus is an excellent way to derive the timing ramp for the PWM stage.

Generating V_{DD}

After turning on the FAN4800AS/CS/01S/02S at 11V, the operating voltage can vary from 9.3V to 28V. The threshold voltage of the V_{DD} OVP comparator is 28V and its hysteresis is 1V. When V_{DD} reaches 28V, OPFC is LOW and the PWM section is not disturbed. There are two ways to generate V_{DD} : use auxiliary power supply around 15V or use bootstrap winding to self-bias the FAN4800AS/CS/01S/02S system. The bootstrap winding can be tapped from the PFC boost choke or the transformer of the DC-to-DC stage.

Leading/Trailing Edge Modulation

Conventional PWM techniques employ trailing-edge modulation, in which the switch turns on right after the trailing edge of the system clock. The error amplifier output is then compared with the modulating ramp up. The effective duty cycle of the trailing-edge modulation is determined during the on-time of the switch.

In the case of leading-edge modulation, the switch is turned off exactly at the leading edge of the system clock. When the modulating ramp reaches the level of the error amplifier output voltage, the switch is turned on. The effective duty-cycle of the leading-edge modulation is determined during off-time of the switch.

[ON Semiconductor:](#)

[FAN4802SMY](#) [FAN4802SNY](#)

Компания «Life Electronics» занимается поставками электронных компонентов импортного и отечественного производства от производителей и со складов крупных дистрибьюторов Европы, Америки и Азии.

С конца 2013 года компания активно расширяет линейку поставок компонентов по направлению коаксиальный кабель, кварцевые генераторы и конденсаторы (керамические, пленочные, электролитические), за счёт заключения дистрибьюторских договоров

Мы предлагаем:

- Конкурентоспособные цены и скидки постоянным клиентам.
- Специальные условия для постоянных клиентов.
- Подбор аналогов.
- Поставку компонентов в любых объемах, удовлетворяющих вашим потребностям.
- Приемлемые сроки поставки, возможна ускоренная поставка.
- Доставку товара в любую точку России и стран СНГ.
- Комплексную поставку.
- Работу по проектам и поставку образцов.
- Формирование склада под заказчика.
- Сертификаты соответствия на поставляемую продукцию (по желанию клиента).
- Тестирование поставляемой продукции.
- Поставку компонентов, требующих военную и космическую приемку.
- Входной контроль качества.
- Наличие сертификата ISO.

В составе нашей компании организован Конструкторский отдел, призванный помогать разработчикам, и инженерам.

Конструкторский отдел помогает осуществить:

- Регистрацию проекта у производителя компонентов.
- Техническую поддержку проекта.
- Защиту от снятия компонента с производства.
- Оценку стоимости проекта по компонентам.
- Изготовление тестовой платы монтаж и пусконаладочные работы.
