

# APDS-9190

## Digital Proximity Sensor

## Data Sheet

### Description

The APDS-9190 provides IR LED and a complete digital proximity detection system in a single 8 pin package. The proximity function offers plug and play detection to 100 mm (without front glass) thus eliminating the need for factory calibration of the end equipment or sub-assembly. The proximity detection feature operates well from bright sunlight to dark rooms. The wide dynamic range also allows for operation in short distance detection behind dark glass such as a cell phone.

The proximity function is targeted specifically towards near field proximity applications. In cell phones, the proximity detection can detect when the user positions the phone close to their ear. The device is fast enough to provide proximity information at a high repetition rate needed when answering a phone call. This provides both improved “green” power saving capability and the added security to lock the computer when the user is not present. The addition of the micro-optics lenses within the module, provide highly efficient transmission and reception of infrared energy which lowers overall power dissipation.

### Ordering Information

| Part Number | Packaging   | Quantity      |
|-------------|-------------|---------------|
| APDS-9190   | Tape & Reel | 2500 per reel |

### Features

- IR LED and Proximity Detector in an Optical Module
- Proximity Detection
  - Fully Calibrated to 100 mm Detection
  - Integrated IR LED and Synchronous LED Driver
  - Eliminates “Factory Calibration” of Prox
  - Covers a 2000: 1 Dynamic Range
- Programmable Wait Timer
  - Wait State Power – 70  $\mu$ A Typical
  - Programmable from 2.72 ms to > 6 Sec
- I<sup>2</sup>C Interface Compatible
  - Up to 400 kHz (I<sup>2</sup>C Fast-Mode)
  - Dedicated Interrupt Pin
- Sleep Mode Power - 2.5  $\mu$ A Typical
- Small Package L3.94 x W2.36 x H1.35 mm

### Applications

- Cell Phone Touch-screen Disable
- Notebook/Monitor Security
- Automatic Speakerphone Enable
- Automatic Menu Pop-up
- Digital Camera Eye Sensor

## Functional Block Diagram

## Detailed Description

The APDS-9190 light-to-digital device provides on-chip Ch0 and CH1 diodes, integrating amplifiers, ADCs, accumulators, clocks, buffers, comparators, a state machine and an I<sup>2</sup>C interface. Each device combines one Ch0 photodiode (visible plus infrared) and one infrared-responding (IR) photodiode. Two integrating ADCs simultaneously convert the amplified photodiode currents to a digital value providing up to 16-bits of resolution. Upon completion of the conversion cycle, the conversion result is transferred to the Ch0 and IR data registers. This digital output can be read by a microprocessor.

Communication to the device is accomplished through a fast (up to 400 kHz), two-wire I<sup>2</sup>C serial bus for easy connection to a microcontroller or embedded controller. The digital output of the APDS-9190 device is inherently more immune to noise when compared to an analog interface.

The APDS-9190 provides a separate pin for level-style interrupts. When interrupts are enabled and a pre-set value is exceeded, the interrupt pin is asserted and remains asserted until cleared by the controlling firmware.

The interrupt feature simplifies and improves system efficiency by eliminating the need to poll a sensor for a proximity value. An interrupt is generated when the value of proximity conversion exceeds either an upper or lower threshold. Additionally, a programmable interrupt persistence feature allows the user to determine how many consecutive exceeded thresholds are necessary to trigger an interrupt. Interrupt thresholds and persistence settings are configured independently for proximity.

Proximity detection is fully provided with an 850 nm IR LED. An internal LED driver (LDR) pin, is jumper connected to the LED cathode (LED K) to provide a factory calibrated proximity of 100 +/- 20 mm. This is accomplished with a proprietary current calibration technique that accounts for all variances in silicon, optics, package and most importantly IR LED output power. This will eliminate or greatly reduce the need for factory calibration that is required for most discrete proximity sensor solutions. While the APDS-9190 is factory calibrated at a given pulse count, the number of proximity LED pulses can be programmed from 1 to 255 pulses, which will allow greater proximity distances to be achieved. Each pulse has a 16  $\mu$ s period.

## I/O Pins Configuration

| Pin | Name | Type | Description                                                                                   |
|-----|------|------|-----------------------------------------------------------------------------------------------|
| 1   | SDA  | I/O  | I <sup>2</sup> C serial data I/O terminal – serial data I/O for I <sup>2</sup> C.             |
| 2   | INT  | O    | Interrupt – open drain.                                                                       |
| 3   | LDR  | I    | LED driver for proximity emitter – up to 100 mA, open drain.                                  |
| 4   | LEDK | O    | LED Cathode, connect to LDR pin in most systems to use internal LED driver circuit            |
| 5   | LEDA | I    | LED Anode, connect to VBATT on PCB                                                            |
| 6   | GND  |      | Power supply ground. All voltages are referenced to GND.                                      |
| 7   | SCL  | I    | I <sup>2</sup> C serial clock input terminal – clock signal for I <sup>2</sup> C serial data. |
| 8   | VDD  |      | Power Supply voltage.                                                                         |

## Absolute Maximum Ratings over operating free-air temperature range (unless otherwise noted)<sup>†</sup>

| Parameter                 | Symbol           | Min  | Max | Units | Conditions |
|---------------------------|------------------|------|-----|-------|------------|
| Power Supply voltage      | V <sub>DD</sub>  |      | 3.8 | V     | 1          |
| Digital voltage range     |                  | -0.5 | 3.8 | V     |            |
| Digital output current    | I <sub>O</sub>   | -1   | 20  | mA    |            |
| Storage temperature range | T <sub>stg</sub> | -40  | 85  | °C    |            |

<sup>†</sup> Stresses beyond those listed under “absolute maximum ratings” may cause permanent damage to the device. These are stress ratings only and functional operation of the device at these or any other conditions beyond those indicated under “recommended operating conditions” is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

Note:

1. All voltages are with respect to GND.

## Recommended Operating Conditions

| Parameter                                                                    | Symbol            | Min | Typ | Max | Units |
|------------------------------------------------------------------------------|-------------------|-----|-----|-----|-------|
| Operating Ambient Temperature                                                | T <sub>A</sub>    | -30 |     | 85  | °C    |
| Supply voltage                                                               | V <sub>DD</sub>   | 2.5 | 3.0 | 3.6 | V     |
| Interface Bus Power Supply Voltage                                           | V <sub>BUS</sub>  |     | 1.8 |     | V     |
| Supply Voltage Accuracy,<br>V <sub>DD</sub> total error including transients |                   | -3  |     | +3  | %     |
| LED Supply Voltage                                                           | V <sub>BATT</sub> | 2.5 |     | 4.5 | V     |

## Operating Characteristics, V<sub>DD</sub> = 3 V, T<sub>A</sub> = 25° C (unless otherwise noted)

| Parameter                           | Symbol            | Min  | Typ | Max  | Units | Test Conditions   |
|-------------------------------------|-------------------|------|-----|------|-------|-------------------|
| Supply current <sup>[1]</sup>       | I <sub>DD</sub>   |      | 175 | 250  | μA    | Active            |
|                                     |                   |      | 70  |      |       | Wait Mode         |
|                                     |                   |      | 2.5 | 4.0  |       | Sleep Mode        |
| INT SDA output low voltage          | V <sub>OL</sub>   | 0    |     | 0.4  | V     | 3 mA sink current |
|                                     |                   | 0    |     | 0.6  |       | 6 mA sink current |
| Leakage current, SDA, SCL, INT Pins | I <sub>LEAK</sub> | -5   |     | 5    | μA    |                   |
| SCL, SDA input high voltage         | V <sub>IH</sub>   | 1.25 |     |      | V     |                   |
| SCL, SDA input low voltage          | V <sub>IL</sub>   |      |     | 0.54 | V     |                   |
| Oscillator frequency                | f <sub>osc</sub>  | 705  | 750 | 795  | kHz   | PON = 1           |

Note:

1. The power consumption is raised by the programmed amount of Proximity LED Drive during the 8 us the LED pulse is on. The nominal and maximum values are shown under Proximity Characteristics. There the I<sub>DD</sub> supply current is I<sub>DD</sub> Active + Proximity LED Drive programmed value.

**Proximity Characteristics,  $V_{DD} = 3\text{ V}$ ,  $T_A = 25^\circ\text{ C}$ , PGAIN=1, PEN = 1 (unless otherwise noted)**

| Parameter                            | Symbol   | Min | Typ  | Max  | Units         | Test Conditions                                                                                                                               |

## Principles of Operation

### System State Machine

The APDS-9190 provides control of proximity detection and power management functionality through an internal state machine. After a power-on-reset, the device is in the sleep mode. As soon as the PON bit is set, the device will move to the start state. It will then continue through the Prox and Wait states. If these states are enabled, the device will execute each function. If the PON bit is set to a 0, the state machine will continue until all conversions are completed and then go into a low power sleep mode.

Note: In this document, the nomenclature uses the bit field name in *italics* followed by the register number and bit number to allow the user to easily identify the register and bit that controls the function. For example, the power on (PON) is in register 0, bit 0. This is represented as PON (r0:b0).

Figure 6. Simplified State Diagram

## Proximity Detection

Proximity sensing uses an internal IR LED light source to emit light which is then viewed by the integrated light detector to measure the amount of reflected light when an object is in the light path. The amount of light detected from a reflected surface can then be used to determine an object's proximity to the sensor. The APDS-9190 is factory calibrated to meet the requirement of proximity sensing of 100 +/- 20 mm, thus eliminating the need for factory calibration of the end equipment. When the APDS-9190 is placed behind a typical glass surface, the proximity detection achieved is around 25 to 40 mm, thus providing an ideal touch-screen disable.

The APDS-9190 has controls for the number of IR pulses (PPCOUNT), the integration time (PTIME), the LED drive current (PDRIVE) and the photodiode configuration (PDIODE). The photodiode configuration can be set to no diode (test mode), infrared diode (recommended), Ch0 diode or a combination of both diodes. At the end of the integration cycle, the results are latched into the proximity data (PDATA) register.

The LED drive current is controlled by a regulated current sink on the LDR pin. This feature eliminates the need to use a current limiting resistor to control LED current. The LED drive current can be configured for 12.5 mA, 25 mA, 50 mA, or 100mA. For higher LED drive requirements, an external P type transistor can be used to control the LED current.

The number of LED pulses can be programmed to a value of 1 to 255 pulses as needed. Increasing the number of LED pulses at a given current will increase the sensor sensitivity. Sensitivity grows by the square root of the number of pulses. Each pulse has a 16  $\mu$ s period.

The proximity integration time (PTIME) is the period of time that the internal ADC converts the analog signal to a digital count. It is recommend that this be set to a minimum of PTIME = 0xFF or 2.72 ms.

Figure 7. Proximity IR LED Waveform

## Optical Design Considerations

The APDS-9190 simplifies the optical system design by eliminating the need for light pipes and improves system optical efficiency by providing apertures and package shielding which will reduce crosstalk when placed in the final system. By reducing the IR LED to glass surface crosstalk, proximity performance is greatly improved and enables a wide range of cell phone applications utilizing the APDS-9190. The module package design has been optimized for minimum package foot print and short distance proximity of 100 mm typical. The spacing between the glass surface and package top surface is critical to controlling the crosstalk. If the package to top surface spacing gap, window thickness and transmittance are met, there should be no need to add additional components (such as a barrier) between the LED and photodiode. Thus with some simple mechanical design implementations, the APDS-9190 will perform well in the end equipment system.

The APDS-9190 is available in a low profile package that contains optics which provides optical gain on both the LED and the sensor side of the package. The device has a package Z height of 1.35 mm and will support air gap of  $\leq 0.5$  mm between the glass and the package. The assumption of the optical system level design is that glass surface above the module is  $\leq$  to 1.0 mm.

By integrating the micro-optics in the package, the IR energy emitted can be reduced thus conserving the precious battery life in the application.

The system designer has the ability to optimize their designs for slim form factor Z height as well as improve the proximity sensing, save battery power and disable the touch screen in a cellular phone.

### APDS-9190 Module Optimized design parameters

- Window thickness,  $t \leq 1.0$  mm
- Air gap,  $g \leq 0.5$  mm
- Assuming window IR transmittance 90%

## Interrupts

The interrupt feature of the APDS-9190 simplifies and improves system efficiency by eliminating the need to poll the sensor for a light intensity or proximity value. The interrupt mode is determined by the PIEN or AIEN field in the ENABLE register.

The APDS-9190 implements four 16-bit-wide interrupt threshold registers that allow the user to define thresholds above and below a desired light level. An interrupt can be generated when the proximity data (PDATA) exceeds the upper threshold value (PIHTx) or falls below the lower threshold (PILTx).

To further control when an interrupt occurs, the APDS-9190 provides an interrupt persistence feature. This feature allows the user to specify a number of conversion cycles for which an event exceeding the proximity interrupt threshold must persist (PPERS) before actually generating an interrupt. Refer to the register descriptions for details on the length of the persistence.

Figure 10. Programmable Interrupt

## State Diagram

The following shows a more detailed flow for the state machine. The device starts in the sleep mode. The PON bit is written to enable the device. If the PEN bit is set, the state machine will step through the proximity states of proximity accumulate and then proximity ADC conversion. As soon as the conversion is complete, the state machine will move to the following state.

If the WEN bit is set, the state machine will then cycle through the wait state. If the WLONG bit is set, the wait cycles are extended by 12x over normal operation.

Figure 11. Extended State Diagram

## Power Management

Power consumption can be controlled through the use of the wait state timing since the wait state consumes only 70  $\mu\text{A}$  of power. The following shows an example of using the power management feature to achieve an average power consumption of 140  $\mu\text{A}$  of current with 4 – 100 mA pulses of proximity detection.

### Example: 50 ms Cycle Time

| State                                                                                            | Duration      | Current(mA) |
|--------------------------------------------------------------------------------------------------|---------------|-------------|
| Prox Accum (LED On)                                                                              | 0.064 (0.032) | 100         |
| Prox ADC                                                                                         | 2.72          | 0.175       |
| Wait                                                                                             | 47            | 0.070       |
| Avg = $((0.032 \times 100) + (2.72 \times 0.175) + (47 \times 0.070)) \div 50 = 140 \mu\text{A}$ |               |             |

## BASIC SOFTWARE OPERATION

The following pseudo-code shows how to do basic initialization of the APDS-9190.

```
uint8 PTIME, WTIME, PPCOUNT;

WTIME = 0xff; // 2.7ms – minimum Wait time
PTIME = 0xff; // 2.7ms – minimum Prox integration time
PPCOUNT = 1; // Minimum prox pulse count

WriteRegData(0, 0); //Disable and Powerdown
WriteRegData(2, PTIME);
WriteRegData(3, WTIME);
WriteRegData(0xe, PPCOUNT);

uint8 PDRIVE, PDIODE, PGAIN, AGAIN;
PDRIVE = 0; //100mA of LED Power
PDIODE = 0x20; // Ch1 Diode
PGAIN = 0; //1x Prox gain
WriteRegData(0xf, PDRIVE | PDIODE | PGAIN | AGAIN);

uint8 WEN, PEN, PON;
WEN = 8; // Enable Wait
PEN = 4; // Enable Prox
PON = 1; // Enable Power On
WriteRegData(0, WEN | PEN | PON); // WriteRegData(0,0x0f);

Wait(12); //Wait for 12 ms

int Prox_data;

Prox_data = Read_Word(0x18);

WriteRegData(uint8 reg, uint8 data)
{
    m_I2CBus.Writel2C(0x39, 0x80 | reg, 1, &data);
}

uint16 Read_Word(uint8 reg);
{
    uint8 barr[2];
    m_I2CBus.Readl2C(0x39, 0xA0 | reg, 2, ref barr);
    return (uint16)(barr[0] + 256 * barr[1]);
}
```

## I<sup>2</sup>C Protocol

Interface and control of the APDS-9190 is accomplished through an I<sup>2</sup>C serial compatible interface (standard or fast mode) to a set of registers that provide access to device control functions and output data. The device supports a single slave address of 0x39 hex using 7 bit addressing protocol. (Contact factory for other addressing options.)

The I<sup>2</sup>C standard provides for three types of bus transaction: read, write and a combined protocol. During a write operation, the first byte written is a command byte followed by data. In a combined protocol, the first byte written is the command byte followed by reading a series

of bytes. If a read command is issued, the register address from the previous command will be used for data access. Likewise, if the MSB of the command is not set, the device will write a series of bytes at the address stored in the last valid command with a register address. The command byte contains either control information or a 5 bit register address. The control commands can also be used to clear interrupts. For a complete description of I<sup>2</sup>C protocols, please review the I<sup>2</sup>C Specification at: <http://www.NXP.com>

## Register Set

The APDS-9190 is controlled and monitored by data registers and a command register accessed through the serial interface. These registers provide for a variety of control functions and can be read to determine results of the ADC conversions.

| Address | Register Name | R/W | Register Function                          | Reset Value |
|---------|---------------|-----|--------------------------------------------|-------------|
| –       | COMMAND       | W   | Specifies register address                 | 0x00        |
| 0x00    | ENABLE        | R/W | Enable of states and interrupts            | 0x00        |
| 0x02    | PTIME         | R/W | Proximity ADC time                         | 0xFF        |
| 0x03    | WTIME         | R/W | Wait time                                  | 0xFF        |
| 0x08    | PILTL         | R/W | Proximity interrupt low threshold low byte | 0x00        |
| 0x09    | PILTH         | R/W | Proximity interrupt low threshold hi byte  | 0x00        |
| 0x0A    | PIHTL         | R/W | Proximity interrupt hi threshold low byte  | 0x00        |
| 0x0B    | PIHTH         | R/W | Proximity interrupt hi threshold hi byte   | 0x00        |
| 0x0C    | PERS          | R/W | Interrupt persistence filters              | 0x00        |
| 0x0D    | CONFIG        | R/W | Configuration                              | 0x00        |
| 0x0E    | PPCOUNT       | R/W | Proximity pulse count                      | 0x00        |
| 0x0F    | CONTROL       | R/W | Gain control register                      | 0x00        |
| 0x11    | REV           | R   | Revision Number                            | Rev         |
| 0x13    | STATUS        | R   | Device status                              | 0x00        |
| 0x18    | PDATA_L       | R   | Proximity ADC low data register            | 0x00        |
| 0x19    | PDATA_H       | R   | Proximity ADC high data register           | 0x00        |

The mechanics of accessing a specific register depends on the specific protocol used. See the section on I<sup>2</sup>C protocols on the previous pages. In general, the COMMAND register is written first to specify the specific control/status register for following read/write operations.

## Command Register

The command registers specifies the address of the target register for future write and read operations.

| 00101       | Proximity interrupt clear                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |             |                  |       |                                    |       |                                     |       |                           |       |                                          |
| 00111       | Proximity interrupt clear                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |             |                  |       |                                    |       |                                     |       |                           |       |                                          |
| other       | Reserved – Do not write                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |             |                  |       |                                    |       |                                     |       |                           |       |                                          |

## Enable Register (0x00)

The ENABLE register is used primarily to power the APDS-9190 device up and down as shown in Table 4.

|               |          |          |      |          |     |     |          |     |         |

| Field    | Bits | Description                                                                                                                                                                       |
|----------|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Reserved | 7:6  | Reserved. Write as 0.                                                                                                                                                             |
| PIEN     | 5    | Proximity Interrupt Enable. When asserted, permits proximity interrupts to be generated.                                                                                          |
| Reserved | 4    | Reserved. Write as 0.                                                                                                                                                             |
| WEN      | 3    | Wait Enable. This bit activates the wait feature. Writing a 1 activates the wait timer. Writing a 0 disables the wait timer.                                                      |
| PEN      | 2    | Proximity Enable. This bit activates the proximity function. Writing a 1 enables proximity. Writing a 0 disables proximity.                                                       |
| Reserved | 1    | Reserved. Write as 0.                                                                                                                                                             |
| PON      | 0    | Power ON. This bit activates the internal oscillator to permit the timers and ADC channels to operate. Writing a 1 activates the oscillator. Writing a 0 disables the oscillator. |

Notes:

1. A 2.7-ms delay is automatically inserted prior to entering the ADC cycle, independent of the WEN bit.
2. PON must be asserted before the ADC channels will operate correctly.
3. During writes and reads over the I<sup>2</sup>C interface, this bit is overridden and the oscillator is enabled, independent of the state of PON.
4. A minimum interval of 2.7 ms must pass after PON is asserted before proximity can be initiated. This required time is enforced by the hardware in cases where the firmware does not provide it.

### Proximity Time Control Register (0x02)

The proximity timing register controls the integration time of the proximity ADC in 2.72 ms increments. It is recommended that this register be programmed to a value of 0xff (1 cycle, 1023 bits).

| Field | Bits | Description |        |         |           |
|-------|------|-------------|--------|---------|-----------|
| PTIME | 7:0  | Value       | Cycles | Time    | Max Count |
|       |      | 0xff        | 1      | 2.72 ms | 1023      |

### Wait Time Register (0x03)

Wait time is set 2.72 ms increments unless the WLONG bit is asserted in which case the wait times are 12x longer. WTIME is programmed as a 2's complement number.

| Field | Bits | Description    |           |                  |                  |
|-------|------|----------------|-----------|------------------|------------------|
| WTIME | 7:0  | Register Value | Wait Time | Time (WLONG = 0) | Time (WLONG = 1) |
|       |      | 0xff           | 1         | 2.72 ms          | 0.032 sec        |
|       |      | 0xb6           | 74        | 201.29 ms        | 2.37 sec         |
|       |      | 0x00           | 256       | 696.32 ms        | 8.19 sec         |

Notes:

1. The Write Byte protocol cannot be used when WTIME is greater than 127.
2. The Proximity Wait Time Register should be configured before PEN is asserted.

### Proximity Interrupt Threshold Register (0x08 – 0x0B)

The proximity interrupt threshold registers provide the values to be used as the high and low trigger points for the comparison function for interrupt generation. If the value generated by proximity channel crosses below the lower threshold specified, or above the higher threshold, an interrupt is signaled to the host processor.

| Register | Address | Bits | Description                                     |
|----------|---------|------|-------------------------------------------------|
| PILTL    | 0x08    | 7:0  | Proximity ADC channel low threshold lower byte  |
| PILTH    | 0x09    | 7:0  | Proximity ADC channel low threshold upper byte  |
| PIHTL    | 0x0A    | 7:0  | Proximity ADC channel high threshold lower byte |
| PIHTH    | 0x0B    | 7:0  | Proximity ADC channel high threshold upper byte |

### Persistence Register (0x0C)

The persistence register controls the filtering interrupt capabilities of the device. Configurable filtering is provided to allow interrupts to be generated after each ADC integration cycle or if the ADC integration has produced a result that is outside of the values specified by threshold register for some specified amount of time.

| Field | Bits | Description                                                                                  |                |                                              |
|-------|------|----------------------------------------------------------------------------------------------|----------------|----------------------------------------------|
| PPERS | 7:4  | Proximity interrupt persistence. Controls rate of proximity interrupt to the host processor. |                |                                              |
|       |      | <b>Field Value</b>                                                                           | <b>Meaning</b> | <b>Interrupt Persistence Function</b>        |
|       |      | 0000                                                                                         | Every          | Every proximity cycle generates an interrupt |
|       |      | 0001                                                                                         | 1              | 1 consecutive proximity values out of range  |
|       |      | ...                                                                                          | ...            | ...                                          |
|       |      | 1111                                                                                         | 15             | 15 consecutive proximity values out of range |

### Configuration Register (0x0D)

The configuration register sets the wait long time.

| Field    | Bits | Description                                                                                                         |
|----------|------|---------------------------------------------------------------------------------------------------------------------|
| Reserved | 7:2  | Reserved. Write as 0.                                                                                               |
| WLONG    | 1    | Wait Long. When asserted, the wait cycles are increased by a factor 12x from that programmed in the WTIME register. |
| Reserved | 0    | Reserved. Write as 0.                                                                                               |

### Proximity Pulse Count Register (0x0E)

The proximity pulse count register sets the number of proximity pulses that will be transmitted. PPCOUNT defines the number of pulses to be transmitted at a 62.5 kHz rate.

| Field   | Bits | Description                                                                      |
|---------|------|----------------------------------------------------------------------------------|
| PPCOUNT | 7:0  | Proximity Pulse Count. Specifies the number of proximity pulses to be generated. |

## Control Register (0x0F)

The Gain register provides eight bits of miscellaneous control to the analog block. These bits typically control functions such as gain settings and/or diode selection.

|                |        |   |        |   |       |   |          |   |      |
|----------------|--------|---|--------|---|-------|---|----------|---|------|

| Reserved | 1:0  | Reserved. Write as 0.                          |

## Rev ID Register (0x11)

The Rev ID register provides the silicon revision number. The Rev ID is a read-only register whose value never changes.

|            |        |   |   |   |   |   |   |   |      |
|------------|--------|---|---|---|---|---|---|---|------|
|            | 7      | 6 | 5 | 4 | 3 | 2 | 1 | 0 |      |
| <b>REV</b> | REV ID |   |   |   |   |   |   |   | 0x11 |

| Field  | Bits | Description                    |
|--------|------|--------------------------------|
| REV ID | 7:0  | Revision number identification |
|        |      | 0x01                           |

## Status Register (0x13)

The Status Register provides the internal status of the device. This register is read only.

|               |          |          |      |          |          |          |        |          |      |
|---------------|----------|----------|------|----------|----------|----------|--------|----------|------|
|               | 7        | 6        | 5    | 4        | 3        | 2        | 1      | 0        |      |
| <b>STATUS</b> | Reserved | Reserved | PINT | Reserved | Reserved | Reserved | PVALID | Reserved | 0x13 |

| Field    | Bits | Description                                                                        |
|----------|------|------------------------------------------------------------------------------------|
| Reserved | 7:6  | Reserved.                                                                          |
| PINT     | 5    | Proximity Interrupt. Indicates that the device is asserting a proximity interrupt. |
| Reserved | 4:2  | Reserved.                                                                          |
| PVALID   | 1    | Proximity Interrupt. Indicates that the device is asserting a proximity interrupt. |
| Reserved | 0    | Reserved.                                                                          |

## Proximity DATA Register (0x18 – 0x19)

Proximity data is stored as a 16-bit value. To ensure the data is read correctly, a two byte read I<sup>2</sup>C transaction should be utilized with a read word protocol bit set in the command register. With this operation, when the lower byte register is read, the upper eight bits are stored into a shadow register, which is read by a subsequent read to the upper byte. The upper register will read the correct value even if additional ADC integration cycles end between the reading of the lower and upper registers.

| Register | Address | Bits | Description              |
|----------|---------|------|--------------------------|
| PDATA    | 0x18    | 7:0  | Proximity data low byte  |
| PDATAH   | 0x19    | 7:0  | Proximity data high byte |

## Application Information: Hardware

The application hardware circuit for implementing Proximity system solution is quite simple with the APDS-9190 and is shown in following figure. The 1  $\mu$ F decoupling capacitors should be low ESR to reduce noise. It further recommended to maximize system performance the use of power and ground planes is recommended in the PCB. If mounted on a flexible circuit, the power and ground traces back to the PCB should be sufficiently wide enough to have a low resistance, such as < 1 ohm.

Figure 13. Circuit implementation for Proximity solution using the APDS-9190

## Package Outline Dimensions

## PCB Pad Layout

Suggested PCB pad layout guidelines for the Dual Flat No-Lead surface mount package are shown below.

Notes: all linear dimensions are in mm.

## Tape Dimensions

## Reel Dimensions

All dimensions unit: mm

## Moisture Proof Packaging

All APDS-9190 options are shipped in moisture proof package. Once opened, moisture absorption begins. This part is compliant to JEDEC MSL 3.

### Baking Conditions:

| Package  | Temp.  | Time     |
|----------|--------|----------|
| In Reels | 60° C  | 48 hours |
| In Bulk  | 100° C | 4 hours  |

If the parts are not stored in dry conditions, they must be baked before reflow to prevent damage to the parts.

Baking should only be done once.

### Recommended Storage Conditions:

|                     |                |
|---------------------|----------------|
| Storage Temperature | 10° C to 30° C |
| Relative Humidity   | Below 60% RH   |

### Time from unsealing to soldering:

After removal from the bag, the parts should be soldered within 168 hours if stored at the recommended storage conditions. If times longer than 168 hours are needed, the parts must be stored in a dry box

## Recommended Reflow Profile

| Process Zone                                 | Symbol | $\Delta T$       | Maximum $\Delta T / \Delta \text{time or Duration}$ |
|----------------------------------------------|--------|------------------|-----------------------------------------------------|
| Heat Up                                      | P1, R1 | 25° C to 150° C  | 3°C/s                                               |
| Solder Paste Dry                             | P2, R2 | 150° C to 200° C | 100 s to 180 s                                      |
| Solder Reflow                                | P3, R3 | 200° C to 260° C | 3°C/s                                               |
|                                              | P3, R4 | 260° C to 200° C | -6°C/s                                              |
| Cool Down                                    | P4, R5 | 200° C to 25° C  | -6°C/s                                              |
| Time maintained above liquidus point, 217° C |        | > 217° C         | 60 s to 120 s                                       |
| Peak Temperature                             |        | 260° C           | –                                                   |
| Time within 5° C of actual Peak Temperature  |        | > 255° C         | 20 s to 40 s                                        |
| Time 25° C to Peak Temperature               |        | 25° C to 260° C  | 8 mins                                              |

The reflow profile is a straight-line representation of a nominal temperature profile for a convective reflow solder process. The temperature profile is divided into four process zones, each with different  $\Delta T / \Delta \text{time}$  temperature change rates or duration. The  $\Delta T / \Delta \text{time}$  rates or duration are detailed in the above table. The temperatures are measured at the component to printed circuit board connections.

In **process zone P1**, the PC board and component pins are heated to a temperature of 150°C to activate the flux in the solder paste. The temperature ramp up rate, R1, is limited to 3°C per second to allow for even heating of both the PC board and component pins.

**Process zone P2** should be of sufficient time duration (100 to 180 seconds) to dry the solder paste. The temperature is raised to a level just below the liquidus point of the solder.

**Process zone P3** is the solder reflow zone. In zone P3, the temperature is quickly raised above the liquidus point of

solder to 260°C (500°F) for optimum results. The dwell time above the liquidus point of solder should be between 60 and 120 seconds. This is to assure proper coalescing of the solder paste into liquid solder and the formation of good solder connections. Beyond the recommended dwell time the intermetallic growth within the solder connections becomes excessive, resulting in the formation of weak and unreliable connections. The temperature is then rapidly reduced to a point below the solidus temperature of the solder to allow the solder within the connections to freeze solid.

**Process zone P4** is the cool down after solder freeze. The cool down rate, R5, from the liquidus point of the solder to 25°C (77°F) should not exceed 6°C per second maximum. This limitation is necessary to allow the PC board and component pins to change dimensions evenly, putting minimal stresses on the component.

It is recommended to perform reflow soldering no more than twice.

For product information and a complete list of distributors, please go to our web site: [www.avagotech.com](http://www.avagotech.com)

Компания «Life Electronics» занимается поставками электронных компонентов импортного и отечественного производства от производителей и со складов крупных дистрибьюторов Европы, Америки и Азии.

С конца 2013 года компания активно расширяет линейку поставок компонентов по направлению коаксиальный кабель, кварцевые генераторы и конденсаторы (керамические, пленочные, электролитические), за счёт заключения дистрибьюторских договоров

Мы предлагаем:

- Конкурентоспособные цены и скидки постоянным клиентам.
- Специальные условия для постоянных клиентов.
- Подбор аналогов.
- Поставку компонентов в любых объемах, удовлетворяющих вашим потребностям.
- Приемлемые сроки поставки, возможна ускоренная поставка.
- Доставку товара в любую точку России и стран СНГ.
- Комплексную поставку.
- Работу по проектам и поставку образцов.
- Формирование склада под заказчика.
- Сертификаты соответствия на поставляемую продукцию (по желанию клиента).
- Тестирование поставляемой продукции.
- Поставку компонентов, требующих военную и космическую приемку.
- Входной контроль качества.
- Наличие сертификата ISO.

В составе нашей компании организован Конструкторский отдел, призванный помогать разработчикам, и инженерам.

Конструкторский отдел помогает осуществить:

- Регистрацию проекта у производителя компонентов.
- Техническую поддержку проекта.
- Защиту от снятия компонента с производства.
- Оценку стоимости проекта по компонентам.
- Изготовление тестовой платы монтаж и пусконаладочные работы.
