General Description

The HV2802 is a low charge injection, 32-channel, high voltage analog switch intended for use in applications requiring high voltage switching controlled by low voltage control signals, such as medical ultrasound imaging, driving piezoelectric transducers, and printers. The bleed resistors eliminate voltage built up on capacitive loads such as piezoelectric transducers.

Input data are shifted into a 32-bit shift registers that can then be retained in a 32-bit latch. To reduce any possible clock feed through noise, the latch enable bar should be left high until all bits are clocked in. Data are clocked in during the rising edge of the clock. Using HVCMOS technology, this device combines high voltage bilateral DMOS switches and low power CMOS logic to provide efficient control of high voltage analog signals.

The device is suitable for various combinations of high voltage supplies, e.g., V_{PP}/V_{NN}: +40V/-160V, +100V/-100V, and +160V/-40V.

Notes:

1. *The 32 switches operate independently.*
2. *Serial data is clocked in on the L to H transition of the CLK.*
3. *All 32 switches go to a state retaining their latched condition at the rising edge of $\overline{LE}$. When $\overline{LE}$ is low the shift registers data flow through the latch.*
4. *D_{OUT} is high when data in the register 31 is high.*
5. *Shift registers clocking has no effect on the switch states if $\overline{LE}$ is high.*
6. *The CLR clear input overrides all other inputs.*
