

## SLLIMM™ -nano small low-loss intelligent molded module IPM, 3 A, 600 V, 3-phase IGBT inverter bridge

Datasheet - production data

### Applications

- 3-phase inverters for motor drives
- Dish washers, refrigerator compressors, heating systems, air-conditioning fans, draining and recirculation pumps

### Description

This SLLIMM (small low-loss intelligent molded module) nano provides a compact, high performance AC motor drive in a simple, rugged design. It is composed of six MOSFETs and three half-bridge HVICs for gate driving, providing low electromagnetic interference (EMI) characteristics with optimized switching speed. The package is optimized for thermal performance and compactness in built-in motor applications, or other low power applications where assembly space is limited. This IPM includes an operational amplifier, completely uncommitted, and a comparator that can be used to design a fast and efficient protection circuit. SLLIMM™ is a trademark of STMicroelectronics.

### Features

- IPM 3 A, 600 V, 3-phase IGBT inverter bridge including control ICs for gate driving and freewheeling diodes
- Optimized for low electromagnetic interference
- $V_{CE(sat)}$  negative temperature coefficient
- 3.3 V, 5 V, 15 V CMOS/TTL input comparators with hysteresis and pull-down/pull-up resistors
- Undervoltage lockout
- Internal bootstrap diode
- Interlocking function
- Smart shutdown function
- Comparator for fault protection against overtemperature and overcurrent
- Op-amp for advanced current sensing
- Optimized pinout for board layout
- NTC for temperature control (UL 1434 CA 2 and 4)

## 4 Smart shutdown function

The device integrates a comparator for fault sensing purposes. The comparator has an internal voltage reference  $V_{REF}$  connected to the inverting input, while the non-inverting input on pin (C<sub>IN</sub>) can be connected to an external shunt resistor for simple overcurrent protection.

When the comparator triggers, the device goes to the shutdown state and both of its outputs are set to low level, causing the half-bridge to enter tri-state.

In common overcurrent protection architectures, the comparator output is usually connected to the shutdown input through an RC network so to provide a monostable circuit which implements a protection time following to a fault condition.

Our smart shutdown architecture immediately turns off the output gate driver in case of overcurrent through a preferential path for the fault signal, which directly switches off the outputs. The time delay between the fault and output shutdown no longer depends on the RC values of the external network connected to the shutdown pin. At the same time, the DMOS connected to the open-drain output (pin T/  $\overline{SD}$  /OD) is turned on by the internal logic, which holds it on until the shutdown voltage is lower than the minimum value of logic input threshold ( $V_{il}$ ).

Besides, the smart shutdown function allows the real disable time to be increased while the constant time of the external RC network remains as it is.

An NTC thermistor for temperature monitoring is internally connected in parallel to the  $\overline{SD}$  pin. To avoid undesired shutdown, keep the voltage  $V_{T/\overline{SD}/OD}$  higher than the high level logic threshold by setting the pull-up resistor  $R_{\overline{SD}}$  to 1 k $\Omega$  or 2.2 k $\Omega$  for the 3.3 V or 5 V MCU power supplies, respectively.

## 5.1 Guidelines

- Input signals HIN, LIN are active high logic. A 375 k $\Omega$  (typ.) pull-down resistor is built-in for each input. To avoid the input signal oscillation, the wiring of each input should be as short as possible and the use of RC filters ( $R_1$ ,  $C_1$ ) on each input signal is suggested. The filters should be with a time constant of about 100 ns and placed as close as possible to the IPM input pins.
  - The use of a bypass capacitor  $C_{VCC}$  (aluminum or tantalum) can help to reduce the transient circuit demand on the power supply. Besides, to reduce high frequency switching noise distributed on the power lines, a decoupling capacitor  $C_2$  (100 to 220 nF, with low ESR and low ESL) should be placed as close as possible to  $V_{CC}$  pin and in parallel with the bypass capacitor.
  - The use of an RC filter ( $R_{SF}$ ,  $C_{SF}$ ) is recommended to avoid protection circuit malfunction. The time constant ( $R_{SF} \times C_{SF}$ ) should be set to 1  $\mu$ s and the filter must be placed as close as possible to the  $C_{IN}$  pin.
  - The  $\overline{SD}$  is an input/output pin (open-drain type if it is used as output). A built-in thermistor NTC is internally connected between the  $\overline{SD}$  pin and GND. The voltage  $V_{SD-GND}$  decreases as the temperature increases, due to the pull-up resistor  $R_{SD}$ . In order to keep the voltage always higher than the high level logic threshold, the pull-up resistor is suggested to be set to 1 k $\Omega$  or 2.2 k $\Omega$  for 3.3 V or 5 V MCU power supply, respectively. The  $C_{SD}$  capacitor of the filter on  $\overline{SD}$  should be fixed no higher than 3.3 nF to ensure the  $\overline{SD}$  activation time  $\tau_1 \leq 500$  ns; the filter should be placed as close as possible to the  $\overline{SD}$  pin.
  - The decoupling capacitor  $C_3$  (from 100 to 220 nF, ceramic with low ESR and low ESL), in parallel with each  $C_{boot}$ , filters the high frequency disturbance. Both  $C_{boot}$  and  $C_3$  (if present) should be placed as close as possible to the U, V, W and  $V_{boot}$  pins. Bootstrap negative electrodes should be connected to U, V, W terminals directly and separated from the main output wires.
  - To prevent the overvoltage on  $V_{CC}$  pin, a Zener diode (Dz1) can be used. Similarly on the  $V_{boot}$  pin, a Zener diode (Dz2) can be placed in parallel with each  $C_{boot}$ .
  - The use of the decoupling capacitor  $C_4$  (100 to 220 nF, with low ESR and low ESL) in parallel with the electrolytic capacitor  $C_{vdc}$  avoids surge destruction. Both capacitors  $C_4$  and  $C_{vdc}$  should be placed as close as possible to the IPM ( $C_4$  has priority over  $C_{vdc}$ ).
  - By integrating an application specific type HVIC inside the module, direct coupling to the MCU terminals without an optocoupler is possible.
  - Low inductance shunt resistors should be used for phase leg current sensing.
  - In order to avoid malfunctions, the wiring among N pins, the shunt resistor and PWR\_GND should be as short as possible.
- These guidelines ensure the specifications of the device for the application design. For further details, please refer to the relevant application note AN4043.
