

Description

The F0424 is a 600MHz to 4200MHz SiGe High-Gain Broadband RF Amplifier. The combination of low noise figure (NF) and high linearity performance allows the device to be used in both receiver and transmitter applications.

The F0424 is designed to operate with a single 5V or 3.3V power supply using a nominal 70mA of I_{CC} . With a supply voltage of 5V, the F0424 provides 17.3dB gain with +40dBm OIP3 and 2.3dB noise figure at 2600MHz.

The device is packaged in a 2×2 mm, 8-pin Thin DFN with 50Ω single-ended RF input and output impedances for ease of integration into the signal path.

Pin Descriptions

Table 2. Pin Descriptions

Number	Name	Description
1	VCC	Power supply. The bypass capacitor must be as close to the pin as possible.
2	RFIN	RF input internally matched to 50Ω. An external DC block is required.
3	NC	No connection. This pin can be left unconnected, connected to VCC, or connected to GND. IDT recommends connecting it to GND.
4	RSET	Main amplifier current bias setting resistor. Connect to GND.
5	RDSET	Distortion amplifier current bias setting resistor. Connect to GND.
6	STBY	Standby. If this pin is not connected or is logic LOW, the device will operate under its normal operating condition. If this pin is logic HIGH, the F0424 will be in STBY Mode.
7	RFOUT	RF output internally matched to 50Ω. An external DC block is required.
8	i.c.	Connect this pin directly to ground.
	EPAD	Exposed pad. This pad is internally connected to GND. Solder this exposed pad to a printed circuit board (PCB) pad that uses multiple ground vias to provide heat transfer out of the device into the PCB ground planes. These multiple ground vias are also required to achieve the specified RF performance.

Absolute Maximum Ratings

The absolute maximum ratings are stress ratings only. Stresses greater than those listed below can cause permanent damage to the device. Functional operation of the F0424 at absolute maximum ratings is not implied. Exposure to absolute maximum rating conditions may affect device reliability.

[a] Exposure to these maximum RF levels can result in significant V_{CC} current draw due to overdriving the amplifier stages.

Applications Information

Power Supplies

A common V_{CC} power supply should be used for all pins requiring DC power. All supply pins should be bypassed with external capacitors to minimize noise and fast transients. Supply noise can degrade the noise figure, and fast transients can trigger ESD clamps and cause them to fail. Supply voltage change or transients should have a slew rate smaller than $1V/20\mu S$. In addition, all control pins should remain at 0V ($\pm 0.3V$) while the supply voltage ramps or while it returns to zero.

If control signal integrity is a concern and clean signals cannot be guaranteed due to overshoot, undershoot, ringing, etc., the following circuit at the input of the STBY control pin is recommended. This applies to the STBY pin as shown below. Note the recommended resistor and capacitor values do not necessarily match the EVKit BOM for the case of poor control signal integrity. For multiple devices driven by a single control line, the component values will need to be adjusted accordingly so as not to load down the control line.
