## PRODUCT DESCRIPTION

The AD 698 is a complete, monolithic Linear Variable Differential T ransformer (LVDT) signal conditioning subsystem. It is used in conjunction with LVDTs to convert transducer mechanical position to a unipolar or bipolar dc voltage with a high degree of accuracy and repeatability. All circuit functions are included on the chip. With the addition of a few external passive components to set frequency and gain, the AD 698 converts the raw LVDT output to a scaled dc signal. The device will operate with half-bridge LVDT s, LVDT s connected in the series opposed configuration (4-wire), and RVDT s.
The AD 698 contains a low distortion sine wave oscillator to drive the LVDT primary. T wo synchronous demodulation channels of the AD 698 are used to detect primary and secondary amplitude. The part divides the output of the secondary by the amplitude of the primary and multiplies by a scale factor. This eliminates scale factor errors due to drift in the amplitude of the primary drive, improving temperature performance and stability.
The AD 698 uses a unique ratiometric architecture to eliminate several of the disadvantages associated with traditional approaches to LVDT interfacing. T he benefits of this new circuit are: no adjustments are necessary; temperature stability is improved; and transducer interchangeability is improved.

The AD 698 is available in two performance grades:

## Grade

AD 698AP
AD 698SQ

Temperature Range
$-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$
$-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$

Package
28-Pin PLCC
24-Pin Cerdip

FUNCTIONAL BLOCK DIAGRAM

## PRODUCT HIGHLIGHTS

1. The AD 698 offers a single chip solution to LVDT signal conditioning problems. All active circuits are on the monolithic chip with only passive components required to complete the conversion from mechanical position to dc voltage.
2. The AD 698 can be used with many different types of position sensors. T he circuit is optimized for use with any LVDT, including half-bridge and series opposed, (4 wire) configurations. The AD 698 accommodates a wide range of input and output voltages and frequencies.
3. The 20 Hz to 20 kHz excitation frequency is determined by a single external capacitor. The AD 698 provides up to 24 volts rms to differentially drive the LVDT primary, and the AD 698 meets its specifications with input levels as low as 100 millivolts rms.
4. C hanges in oscillator amplitude with temperature will not affect overall circuit performance. The AD 698 computes the ratio of the secondary voltage to the primary voltage to determine position and direction. No adjustments are required.
5. Multiple LVDT s can be driven by a single AD 698 either in series or parallel as long as power dissipation limits are not exceeded. The excitation output is thermally protected.
6. The AD 698 may be used as a loop integrator in the design of simple electromechanical servo loops.
7. The sum of the transducer secondary voltages do not need to be constant.

NOTES
${ }^{1} A$ and $B$ represent the $M$ ean Average $D$ eviation (MAD) of the detected sine waves $V_{A}$ and $V_{B}$. The polarity of $V_{\text {OUT }}$ is affected by the sign of the $A$ comparator, i.e., multiply $\mathrm{V}_{\text {OUT }} \times+1$ for $\mathrm{A}_{\text {comp }}>\mathrm{A}_{\text {COMP-, }}$, and $\mathrm{V}_{\text {OUT }} \times-1$ for $\mathrm{A}_{\text {comp- }}>\mathrm{A}_{\text {COMP }+ \text {. }}$
${ }^{2}$ N onlinearity of the AD 698 only in units of ppm of full scale. N onlinearity is defined as the maximum measured deviation of the AD 698 output voltage from a straight line. The straight line is determined by connecting the maximum produced full-scale negative voltage with the maximum produced full-scale positive voltage.
${ }^{3}$ See T ransfer Function.
${ }^{4}$ F or example, if the excitation to the primary changes by 1 dB , the gain of the system will change by typically 100 ppm .
${ }^{5}$ O utput ripple is a function of the AD 698 bandwidth determined by C1 and C2. A 1000 pF capacitor should be connected in parallel with R2 to reduce the output ripple. See Figures 7, 8 and 13.
${ }^{6}$ R1 is shown in Figures 7, 8 and 13.
${ }^{7}$ Excitation voltage drift is not an important specification because of the ratiometric operation of the AD 698.
${ }^{8}$ F rom $T_{\text {MIN }}$ to $T_{\text {MAX }}$ the overall error due to the AD 698 alone is determined by combining gain error, gain drift and offset drift. For example, the typical overall error for the AD 698AP from $T_{\text {MIN }}$ to $T_{\text {MAX }}$ is calculated as follows: Overall Error $=$ Gain Error at $+25^{\circ} \mathrm{C}( \pm 0.2 \%$ Full Scale $)+G$ ain D rift from $-40^{\circ} \mathrm{C}$ to $+25^{\circ} \mathrm{C}$
(20 ppm $/{ }^{\circ} \mathrm{C} \times 65^{\circ} \mathrm{C}$ ) +0 ffset D rift from $-40^{\circ} \mathrm{C}$ to $+25^{\circ} \mathrm{C}\left(5 \mathrm{ppm} /{ }^{\circ} \mathrm{C} \times 65^{\circ} \mathrm{C}\right)= \pm 0.36 \%$ of full scale. N ote that 1000 ppm of full scale equals $0.1 \%$ of full scale.
Specifications subject to change without notice.
Specifications shown in boldface are tested on all production units at final electrical test. Results from those tested are used to calculate outgoing quality levels. All min and max specifications are guaranteed, although only those shown in boldface are tested on all production units.

## CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD 698 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

## THEORY OF OPERATION

A block diagram of the AD 698 along with an LVDT (linear variable differential transformer) connected to its input is shown in Figure 5 below. The LVDT is an electromechanical trans-ducer-its input is the mechanical displacement of a core, and its output is an ac voltage proportional to core position. T wo popular types of LVDT s are the half-bridge type and the series opposed or four-wire LVDT. In both types the moveable core couples flux between the windings. The series-opposed connected LVDT transducer consists of a primary winding energized by an external sine wave reference source and two secondary windings connected in the series opposed configuration. The output voltage across the series secondary increases as the core is moved from the center. The direction of movement is detected by measuring the phase of the output. H alf-bridge LVDT s have a single coil with a center tap and work like an autotransformer. The excitation voltage is applied across the coil; the voltage at the center tap is proportional to position. The device behaves similarly to a resistive voltage divider.

Figure 5. Functional Block Diagram
The AD 698 energizes the LVDT coil, senses the LVDT output voltages and produces a dc output voltage proportional to core position. The AD 698 has a sine wave oscillator and power amplifier to drive the LVDT. T wo synchronous demodulation stages are available for decoding the primary and secondary voltages. A decoder determines the ratio of the output signal voltage to the input drive voltage (A/B). A filter stage and output amplifier are used to scale the resulting output.
The oscillator comprises a multivibrator that produces a triwave output. The triwave drives a sine shaper that produces a low distortion sine wave. F requency and amplitude are determined by a single resistor and capacitor. Output frequency can range from 20 Hz to 20 kHz and amplitude from 2 V to $24 \mathrm{~V} \mathrm{rms} .\mathrm{~T} \mathrm{otal} \mathrm{har-}$ monic distortion is typically -50 dB .
The AD 698 decodes LVDT s by synchronously demodulating the amplitude modulated input (secondaries), $A$, and a fixed input reference (primary or sum of secondaries or fixed input), B. A common problem with earlier solutions was that any drift in the amplitude of the drive oscillator corresponded directly to a
gain error in the output. T he AD 698, eliminates these errors by calculating the ratio of the LVDT output to its input excitation in order to cancel out any drift effects. This device differs from the AD 598 LVDT signal conditioner in that it implements a different circuit transfer function and does not require the sum of the LVDT secondaries $(A+B)$ to be constant with stroke length.
The AD 698 block diagram is shown below. The inputs consist of two independent synchronous demodulation channels. The B channel is designed to monitor the drive excitation to the LVDT. The full wave rectified output is filtered by C2 and sent to the computational circuit. Channel A is identical except that the comparator is pinned out separately. Since the A channel may reach 0 V output at LVDT null, the A channel demodulator is usually triggered by the primary voltage (B Channel). In addition, a phase compensation network may be required to add a phase lead or lag to the A Channel to compensate for the LVDT primary to secondary phase shift. For half-bridge circuits the phase shift is noncritical, and the A channel voltage is large enough to trigger the demodulator.

Figure 6. AD698 Block Diagram
Once both channels are demodulated and filtered a division circuit, implemented with a duty cycle multiplier, is used to calculate the ratio $A / B$. The output of the divider is a duty cycle. When $A / B$ is equal to 1 , the duty cycle will be equal to $100 \%$. (This signal can be used as is if a pulse width modulated output is required.) The duty cycle drives a circuit that modulates and filters a reference current proportional to the duty cycle. The output amplifier scales the $500 \mu \mathrm{~A}$ reference current converting it to a voltage. The output transfer function is thus:

$$
V_{\text {OUT }}=I_{\text {REF }} \times A / B \times R 2, \text { where } I_{\text {REF }}=500 \mu \mathrm{~A}
$$

## CONNECTING THE AD698

The AD 698 can easily be connected for dual or single supply operation as shown in Figures 7, 8 and 13. The following general design procedures demonstrate how external component values are selected and can be used for any LVDT that meets AD 698 input/output criteria. The connections for the $A$ and $B$ channels and the A channel comparators will depend on which transducer is used. In general follow the guidelines below.
Parameters set with external passive components include: excitation frequency and amplitude, AD 698 input signal frequency, and the scale factor (V/inch). Additionally, there are optional features; offset null adjustment, filtering, and signal integration, which can be implemented by adding external components.

Figure 7. Interconnection Diagram for Half-Bridge LVDT and Dual Supply Operation

## DESIGN PROCEDURE

## DUAL SUPPLY OPERATION

Figure 7 shows the connection method for half-bridge LVDTs. Figure 8 demonstrates the connections for 3 - and 4 -wire LVDT s connected in the series opposed configuration. Both examples use dual $\pm 15$ volt power supplies.

## A. Determine the Oscillator Frequency

Frequency is often determined by the required BW of the system. H owever, in some systems the frequency is set to match the LVDT zero phase frequency as recommended by the manufacturer; in this case skip to Step 4.

1. D etermine the mechanical bandwidth required for LVDT position measurement subsystem, $\mathrm{f}_{\text {SUBSYSTEM }}$. For this example, assume $\mathrm{f}_{\text {SUBSYSTEM }}=250 \mathrm{~Hz}$.
2. Select minimum LVDT excitation frequency approximately $10 \times \mathrm{f}_{\text {SUBSYSTEM }}$. Therefore, let excitation frequency $=2.5 \mathrm{kHz}$.
3. Select a suitable LVDT that will operate with an excitation frequency of 2.5 kHz . The Schaevitz E 100, for instance, will operate over a range of 50 Hz to 10 kHz and is an eligible candidate for this example.
4. Select excitation frequency determining component C 1 .

$$
\mathrm{C} 1=35 \mu \mathrm{~F} \mathrm{Hz/f} \text { EXCITATION }
$$

Figure 8. AD698 Interconnection Diagram for Series Opposed LVDT and Dual Supply Operation

## B. Determine the Oscillator Amplitude

A mplitude is set such that the primary signal is in the 1.0 V to 3.5 V rms range and the secondary signal is in the 0.25 V to 3.5 V rms range when the LVDT is at its mechanical full-scale position. This optimizes linearity and minimizes noise susceptibility. Since the part is ratiometric, the exact value of the excitation is relatively unimportant.
5. Determine optimum LVDT excitation voltage, $\mathrm{V}_{\mathrm{EXC}}$. For a 4-wire LVDT determine the voltage transformation ratio, VTR, of the LVDT at its mechanical full scale. VTR = LVDT sensitivity $\times M$ aximum Stroke Length from null.
LVDT sensitivity is listed in the LVDT manufacturer's catalog and has units of volts output per volts input per inch displacement. The E 100 has a sensitivity of $2.4 \mathrm{mV} / \mathrm{V} / \mathrm{mil}$. In the event that LVDT sensitivity is not given by the manufacturer, it can be computed. See section on determining LVDT sensitivity.

M ultiply the primary excitation voltage by the VT R to get the expected secondary voltage at mechanical full scale. F or example, for an LVDT with a sensitivity of $2.4 \mathrm{mV} / \mathrm{N} / \mathrm{mil}$ and a full scale of $\pm 0.1$ inch, the VT $\mathrm{R}=0.0024 \mathrm{~V} / \mathrm{N} / \mathrm{M}$ il $\times 100$ $\mathrm{mil}=0.24$. Assuming the maximum excitation of 3.5 V rms , the maximum secondary voltage will be 3.5 V rms $\times 0.24=$ 0.84 V rms , which is in the acceptable range.

C onversely the VTR may be measured explicitly. With the LVDT energized at its typical drive level $\mathrm{V}_{\text {PRI }}$, as indicated by the manufacturer, set the core displacement to its mechanical full-scale position and measure the output $\mathrm{V}_{\text {SEC }}$ of the secondary. Compute the LVDT voltage transformation ratio, VTR. VTR $=\mathrm{V}_{\text {SEC }} / \mathrm{NPRI}$. For the E100, $\mathrm{V}_{\text {SEC }}=0.72 \mathrm{~V}$ for $\mathrm{V}_{\text {PRI }}=3 \mathrm{~V}$. VTR $=0.24$.
For situations where LVDT sensitivity is low, or the mechanical FS is a small fraction of the total stroke length, an input excitation of more than 3.5 V rms may be needed. In this case a voltage divider network may be placed across the LVDT primary to provide smaller voltage for the +BIN and -BIN input. If, for example, a network was added to divide the $B$ C hannel input by $1 / 2$, then the VT R should also be reduced by $1 / 2$ for the purpose of component selection.
C heck the power supply voltages by verifying that the peak values of $\mathrm{V}_{\mathrm{A}}$ and $\mathrm{V}_{\mathrm{B}}$ are at least 2.5 volts less than the voltages at $+V_{S}$ and $-V_{S}$.
6. Referring to Figure 9 , for $\mathrm{V}_{\mathrm{S}}= \pm 15 \mathrm{~V}$, select the value of the amplitude determining component R1 as shown by the curve in Figure 9.

Figure 9. Excitation Voltage $V_{E X C}$ vs. R1
7. $C 2, C 3$ and $C 4$ are a function of the desired bandwidth of the AD 698 position measurement subsystem. They should be nominally equal values.

$$
\mathrm{C} 2=\mathrm{C} 3=\mathrm{C} 4=10^{-4} \mathrm{~F} \text { arad } \mathrm{H} z / \mathrm{f}_{5 U B S Y S T E M}(\mathrm{~Hz})
$$

If the desired system bandwidth is 250 Hz , then

$$
\mathrm{C} 2=\mathrm{C} 3=\mathrm{C} 4=10^{-4} \mathrm{~F} \text { arad } \mathrm{Hz} / 250 \mathrm{~Hz}=0.4 \mu \mathrm{~F}
$$

See Figures 14, 15 and 16 for more information about AD 698 bandwidth and phase characterization.

## D. Set the Full-Scale Output Voltage

8. T o compute R2, which sets the AD 698 gain or full-scale output range, several pieces of information are needed:
a. LVDT sensitivity, S
b. Full-scale core displacement from null, $d$
$S \times d=$ VTR and also equals the ratio $A / B$ at mechanical full scale. The VT R should be converted to units of V/V.
For a full-scale displacement of $d$ inches, voltage out of the AD 698 is computed as

$$
V_{\text {OUT }}=S \times d \times 500 \mu A \times R 2
$$

$\mathrm{V}_{\text {OUt }}$ is measured with respect to the signal reference,
Pin 21, shown in Figure 7.
Solving for R2,

$$
\begin{equation*}
R 2=\frac{V_{\text {OUT }}}{S \times d \times 500 \mu \mathrm{~A}} \tag{1}
\end{equation*}
$$

For $\mathrm{V}_{\text {OUt }}= \pm 10 \mathrm{~V}$ full-scale range ( 20 V span) and $\mathrm{d}= \pm 0.1$ inch full-scale displacement ( 0.2 inch span)

$$
\mathrm{R} 2=\frac{20 \mathrm{~V}}{2.4 \times 0.2 \times 500 \mu \mathrm{~A}}=83.3 \mathrm{k} \Omega
$$

$V_{\text {out }}$ as a function of displacement for the above example is shown in Figure 10.

Figure 10. $V_{\text {Out }}( \pm 10$ V Full Scale) vs. Core Displacement ( $\pm 0.1$ Inch)

## E. Optional Offset of Output Voltage Swing

9. Selections of R3 and R4 permit a positive or negative output voltage offset adjustment.

$$
\begin{equation*}
\mathrm{V}_{\mathrm{OS}}=1.2 \mathrm{~V} \times \mathrm{R} 2 \times\left(\frac{1}{\mathrm{R} 3+2 \mathrm{k} \Omega}-\frac{1}{\mathrm{R} 4+2 \mathrm{k} \Omega}\right) \tag{2}
\end{equation*}
$$

For no offset adjustment R3 and R4 should be open circuit.
To design a circuit producing a 0 V to +10 V output for a displacement of +0.1 inch, set $\mathrm{V}_{\text {OUT }}$ to $+10 \mathrm{~V}, \mathrm{~d}=0.2$ inch and solve Equation (1) for R2.

Figure 11. V Vut $( \pm 5$ V Full Scale) vs. Core Displacement ( $\pm 0.1$ Inch)
This will produce a response shown in Figure 11.
In Equation (2) set $\mathrm{V}_{0 S}=5 \mathrm{~V}$ and solve for R3 and R4. Since a positive offset is desired, let R4 be open circuit. Rearranging Equation (2) and solving for R3

$$
\mathrm{R} 3=\frac{1.2 \times \mathrm{R} 2}{\mathrm{~V}_{\mathrm{OS}}}-2 \mathrm{k} \Omega=7.02 \mathrm{k} \Omega
$$

$N$ ote that $\mathrm{V}_{\text {OS }}$ should be chosen so that R3 cannot have negative value.
Figure 12 shows the desired response.

Figure 12. Vout (0 V-10 V Full Scale) vs. Displacement ( $\pm 0.1$ Inch)

## DESIGN PROCEDURE

## SINGLE SUPPLY OPERATION

Figure 13 shows the single supply connection method.

Figure 13. Interconnection Diagram for Single Supply Operation
For single supply operation, repeat Steps 1 through 10 of the design procedure for dual supply operation. R5, R 6 and $C 5$ are additional component values to be determined. $\mathrm{V}_{\text {OUt }}$ is measured with respect to SIGNAL REFERENCE.
10. Compute a maximum value of $R 5$ and $R 6$ based upon the relationship

$$
\mathrm{R} 5+\mathrm{R} 6 \leq \mathrm{V}_{\mathrm{PS}} / 100 \mu \mathrm{~A}
$$

11. The voltage drop across $R 5$ must be greater than

$$
2+10 \mathrm{k} \Omega\left(\frac{1.2 \mathrm{~V}}{\mathrm{R} 4+2 \mathrm{k} \Omega}+250 \mu \mathrm{~A}+\frac{\mathrm{V}_{\text {OUT }}}{4 \times \mathrm{R} 2}\right) \mathrm{Volts}
$$

Therefore

$$
R 5 \geq \frac{2+10 \mathrm{k} \Omega\left(\frac{1.2 \mathrm{~V}}{\mathrm{R} 4+2 \mathrm{k} \Omega}+250 \mu \mathrm{~A}+\frac{\mathrm{V}_{0 \cup T}}{4 \times \mathrm{R} 2}\right)}{100 \mu \mathrm{~A}} 0 \mathrm{hms}
$$

Based upon the constraints of R5 + R6 (Step 10) and R5 (Step 11), select an interim value of R6.
12. L oad current through $R_{L}$ returns to the junction of $R 5$ and $R 6$, and flows back to $V_{P S}$. U nder maximum load conditions, make sure the voltage drop across R 5 is met as defined in Step 11.
As a final check on the power supply voltages, verify that the peak values of $V_{A}$ and $V_{B}$ are at least 2.5 volts less than the voltage between $+V_{S}$ and $-V_{S}$.
13. C 5 is a bypass capacitor in the range of $0.1 \mu \mathrm{~F}$ to $1 \mu \mathrm{~F}$.

## Gain Phase Characteristics

To use an LVDT in a closed-loop mechanical servo application, it is necessary to know the dynamic characteristics of the transducer and interface elements. The transducer itself is very quick to respond once the core is moved. The dynamics arise primarily from the interface electronics. Figures 14, 15 and 16 show the frequency response of the AD 698 LVDT Signal C onditioner. N ote that Figures 15 and 16 are basically the same; the difference is frequency range covered. Figure 15 shows a wider range of mechanical input frequencies at the expense of accuracy.

Figure 14. Gain and Phase Characteristics vs. Frequency (0 kHz-10 kHz)

Figure 15. Gain and Phase Characteristics vs. Frequency ( $0 \mathrm{kHz}-50 \mathrm{kHz}$ )

Figure 16. Gain and Phase Characteristics vs. Frequency (0 kHz-10 kHz)

Figure 16 shows a more limited frequency range with enhanced accuracy. The figures are transfer functions with the input to be considered as a sinusoidally varying mechanical position and the output as the voltage from the AD 698; the units of the transfer function are volts per inch. The value of C2, C 3, and C 4, from Figure 7, are all equal and designated as a parameter in the figures. The response is approximately that of two real poles. H owever, there is appreciable excess phase at higher frequencies. An additional pole of filtering can be introduced with a shunt capacitor across R2, Figure 7; this will also increase phase lag.
When selecting values of C2, C3 and C4 to set the bandwidth of the system, a trade-off is involved. There is ripple on the "dc" position output voltage, and the magnitude is determined by the filter capacitors. G enerally, smaller capacitors will give higher system bandwidth and larger ripple. Figures 17 and 18 show the magnitude of ripple as a function of C2, C3 and C4, again all equal in value. N ote also a shunt capacitor across R2, F igure 7 , is shown as a parameter. The value of $R 2$ used was $81 \mathrm{k} \Omega$ with a Schaevitz E100 LVDT.

Figure 17. Output Voltage Ripple vs. Filter Capacitance

Figure 18. Output Voltage Ripple vs. Filter Capacitance

## AD698

## Determining LVDT Sensitivity

LVDT sensitivity can be determined by measuring the LVDT secondary voltages as a function of primary drive and core position, and performing a simple computation.
Energize the LVDT at its recommended primary drive level, $\mathrm{V}_{\text {PRI }}$ ( $3 \mathrm{~V} \mathrm{rms} \mathrm{for} \mathrm{the} \mathrm{E100)}$. mechanical full-scale position and measure secondary voltages $V_{A}$ and $V_{B}$.

$$
\text { Sensitivity }=\frac{\mathrm{V}_{\text {SECONDARY }}}{\mathrm{V}_{\text {PRI }} \times \mathrm{d}}
$$

From Figure 19,

$$
\text { Sensitivity }=\frac{0.72}{3 \mathrm{~V} \times 100 \mathrm{mils}}=2.4 \mathrm{mV} \mathrm{~N} \mathrm{mil}
$$

Figure 19. LVDT Secondary Voltage vs. Core Displacement

## Thermal Shutdown and Loading Considerations

The AD 698 is protected by a thermal overload circuit. If the die temperature reaches $165^{\circ} \mathrm{C}$, the sine wave excitation amplitude gradually reduces, thereby lowering the internal power dissipation and temperature.
Due to the ratiometric operation of the decoder circuit, only small errors result from the reduction of the excitation amplitude. Under these conditions the signal-processing section of the AD 698 continues to meet its output specifications.
The thermal load depends upon the voltage and current delivered to the load as well as the power supply potentials. An LVDT Primary will present an inductive load to the sine wave excitation. T he phase angle between the excitation voltage and current must also be considered, further complicating thermal calculations.

## APPLICATIONS

M ost of the applications for the AD 598 can also be implemented with the AD 698. Please refer to the applications written for the AD 598 for a detailed explanation.

See AD 598 data sheet for:

- Proving Ring-W eigh Scale
- Synchronous Operation of M ultiple LVDTs
- High Resolution Position-to-F requency C ircuit
- L ow Cost Setpoint C ontroller
- M echanical F ollower Servo Loop
- Differential Gaging and Precision Differential Gaging

## AC BRIDGE SIGNAL CONDITIONER

Bridge circuits which use dc excitation are often plagued by errors caused by thermocouple effects, 1/f noise, dc drifts in the electronics, and line noise pickup. One way to get around these problems is to excite the bridge with an ac waveform, amplify the bridge output with an ac amplifier, and synchronously demodulate the resulting signal. The ac phase and amplitude information from the bridge is recovered as a dc signal at the output of the synchronous demodulator. The low frequency system noise, dc drifts, and demodulator noise all get mixed to the carrier frequency and can be removed by means of a lowpass filter.
The AD 698 with the addition of a simple ac gain stage can be used to implement an ac bridge. Figure 20 shows the connections for such a system. The AD 698 oscillator provides ac excitation for the bridge. The low level bridge signal is amplified by the gain stage created by A1, A2 to provide a differential input to the A Channel of the AD 698. The signal is then synchronously detected by A C hannel. The B Channel is used to detect the level of the bridge excitation. The ratio of $A / B$ is then calculated and converted to an output voltage by R2. An optional phase lag/lead network can be added in front of the A comparator to adjust for phase delays through the bridge and the amplifier, or if the phase delay is small, it can be ignored or compensated for by a gain adjustment.
This circuit can be used for resistive bridges such as strain gages, or for inductive or capacitive bridges that are commonly used for pressure or flow sensors. The low level signal outputs of these sensors are susceptible to noise and interference and are good candidates for ac signal processing techniques.

## Component Selection

A mplifiers A1, A2 will be chosen depending on the type of bridge that is conditioned. C apacitive bridges should use an amplifier with low bias current; a large bleeder resistor will be required from the amplifier inputs to ground to provide a path for the dc bias current. Resistive and inductive bridges can use a more general purpose amplifier. The dc performance of A1, A2 are not as important as their ac performance. DC errors such as voltage offset will be chopped out by the AD 698 since they are not synchronous to the carrier frequency.
The oscillator amplitude and span resistor for the AD 698 may be chosen by first computing the transfer function or sensitivity of the bridge and the ac amplifier. This ratio will correspond to the A/B term in the AD 698 transfer function. For example, suppose that a resistive strain gage with a sensitivity, S , of $2 \mathrm{mV} / \mathrm{V}$ at full scale is used. Select an arbitrary target value for $A / B$ that is close to its maximum value such as $A / B=0.8$. Then choose a gain for the ac amplifier so that the strain gage transfer function from excitation to output also equals 0.8. Thus the required amplifier gain will be [A/B]/ S; or 0.8/0.002 V/V $=400$. Then select values for $R_{S}$ and $R_{G}$. For the gain stage:

$$
\mathrm{V}_{\text {OUT }}=\left[\frac{2 \times \mathrm{R}_{\mathrm{S}}}{\mathrm{R}_{\mathrm{G}}+1}\right] \times \mathrm{V}_{\text {IN }}
$$

Solving for $\mathrm{V}_{\text {OUT }} N_{\text {IN }}=400$ and setting $\mathrm{R}_{\mathrm{G}}=100 \Omega$ then:

$$
R_{S}=[400-1] \times R_{G} / 2=19.95 \mathrm{k} \Omega
$$

Choose an oscillator amplitude that is in the range of 1 V to 3.5 V rms. F or an input excitation level of 3 V rms, the output signal from the amplifier gain stage will be $3.5 \mathrm{~V} \mathrm{rms} \times 0.8 \mathrm{~V}$ or 2.4 V rms, which is in the acceptable range.

Since $A / B$ is known, the value of $R 2$, the output FS resistor may be chosen by the formula:

$$
V_{\text {OUT }}=A / B \times 500 \mu A \times R 2
$$

For a 10 V output at FS , with an $\mathrm{A} / \mathrm{B}$ of 0.8 ; solve for R 2 .

$$
\mathrm{R} 2=10 \mathrm{~V}[0.8 \times 500 \mu \mathrm{~A}]=25.0 \mathrm{k} \Omega
$$

This will result in a $\mathrm{V}_{\text {OUt }}$ of 10 V for a full-scale signal from the bridge. The other components, C1, C2, C3, C 4 may be selected by following the guidelines on general device operation mentioned earlier.
If a gain trim is required, then a trim resistor can be used to adjust either R 2 or $\mathrm{R}_{\mathrm{G}}$. Bridge offsets should be adjusted by a trim network on the OFFSET 1 and OFFSET 2 pins of the AD 698.

## OUTLINE DIMENSIONS

Dimensions shown in inches and (mm).

## 24- Pin Cerdip (Wide)

28-Pin PLCC

LifeElectronics
Живое партнерство

Компания «Life Electronics» занимается поставками электронных компонентов импортного и отечественного производства от производителей и со складов крупных дистрибьюторов Европы, Америки и Азии.

С конца 2013 года компания активно расширяет линейку поставок компонентов по направлению коаксиальный кабель, кварцевые генераторы и конденсаторы (керамические, пленочные, электролитические), за счёт заключения дистрибьюторских договоров

Мы предлагаем:

- Конкурентоспособные цены и скидки постоянным клиентам.
- Специальные условия для постоянных клиентов.
- Подбор аналогов.
- Поставку компонентов в любых объемах, удовлетворяющих вашим потребностям.
- Приемлемые сроки поставки, возможна ускоренная поставка.
- Доставку товара в любую точку России и стран СНГ.
- Комплексную поставку.
- Работу по проектам и поставку образцов.
- Формирование склада под заказчика.
- Сертификаты соответствия на поставляемую продукцию (по желанию клиента).
- Тестирование поставляемой продукции.
- Поставку компонентов, требующих военную и космическую приемку.
- Входной контроль качества.
- Наличие сертификата ISO.

В составе нашей компании организован Конструкторский отдел, призванный помогать разработчикам, и инженерам.

Конструкторский отдел помогает осуществить:

- Регистрацию проекта у производителя компонентов.
- Техническую поддержку проекта.
- Защиту от снятия компонента с производства.
- Оценку стоимости проекта по компонентам.
- Изготовление тестовой платы монтаж и пусконаладочные работы.
