

L9680

Automotive advanced airbag IC for mid/high end applications

Features

- AEC-Q100 qualified
- Boost regulator for energy reserve
 - 1.882 MHz operation, I_{load} = 70 mA max
 - Output voltage user selectable, 23 V/ 33 V ±5%
 - Capacitor value & ESR diagnostics
- Boost regulator for PSI-5 SYNC pulse
 - 1.882 MHz operation,
 - Output voltage, 12 V/14.75 V, user configurable
- Buck regulator for remote sensor
 - 1.882 MHz operation
 - Output voltage, 7.2 V/9 V ±4%, user configurable
- Buck regulator for micro controller unit
 - 1.882 MHz operation
 - Output voltage user selectable, 3.3 V or 5.0 V ±3%
- Integrated energy reserve crossover switch
 - 3 Ω 912 mA max
 - Switch active output indicator
- Battery voltage monitor & shutdown control with Wake-up control

Datasheet - production data

- System voltage diagnostics with integrated ADC
- Squib deployment drivers
 - 12 channel HSD/LSD
 - 25 V max deployment voltage
 - Various deployment profiles
 - Current monitoring
 - R_{measure}, STB, STG & Leakage diagnostics
 - High & low side driver FET tests
- High side safing switch regulator and enable control
- Four channel remote sensor interface
 - PSI-5 satellite sensors
 - Active wheel speed sensors
- Three channel GPO, HSD or LSD configurable, with PWM 0-100% control
- Nine channel hall-effect, resistive or switch sensor interface
- User customizable safing logic
- Specific disarm signal for passenger airbag
- Temporal and algorithmic Watchdog timers
- End of life disposal interface
- Temperature sensor
- 32 bit SPI communications
- 5.5 V minimum operating voltage at device battery pin
- Operating temperature, -40 to 95 °C
- Packaging 100 pin

1 Description

The L9680 is an advanced airbag system chip solution targeted for mature airbag market and integrated safety markets. This device is family compatible with the L9678 and L9679 devices. Safety system integration is enabled through higher power supply currents and integrated active wheel speed sensor interface. The active wheel speed interface is shared with the PSI-5 satellite interface to create a generic remote safety sensor interface compliant to both systems.

High frequency power supply design allows further cost reduction by using smaller and less expensive external components. All switching regulators operate at 1.882 MHz while buck converters have integrated synchronous rectifiers.

Additional attention is given to system integrity and diagnostics. The reserve capacitor is electrically isolated from the boost regulator by a 65 mA nominal fixed current source, controlling in-rush an additional capacitor discharge fixed current source is integrated to diagnose the reserve capacitor value and ESR. The same current sources can be used to discharge the capacitor at shutdown.

Thanks to low quiescent current, the device can be directly connected to battery. In this way, the device start-up and shutdown are controlled through the wake-up input function. The power supply and crossover function are controlled automatically through the internal state machine.

The user can select both ECU logic voltage (V_{CC} at 3.3 V or 5.0 V) and energy reserve output voltage (at either 23 V or 33 V). Deployment voltage is set to a maximum of 25 V for all profiles and can be controlled through external safing switch circuit using the high side safing switch reference enabled through the system SPI interface or the arming logic.

2 Absolute maximum ratings

This part may be irreparably damaged if taken outside the specified absolute maximum ratings. Operation above the absolute maximum ratings may also cause a decrease in reliability.

The operating junction temperature range is -40 °C to +150 °C. The maximum junction temperature must not be exceeded except when in deployment and within the deploy power stages. Deployment is possible starting with a junction temperature of 150 °C. A power dissipation calculation has to be performed for the final application limiting the available functionality to a subset of it in order to respect to the power dissipation capability.

1. VBATMON negative AMR is -18 V or -20 mA.

Within the operating ratings the part operates as specified and without parameter deviations. Once taken beyond the operative ratings and returned back within, the part will recover with no damage or degradation.

Additional supply voltage and temperature conditions are given separately at the beginning of each specification table.

4 Pin out

The L9680 pin out is shown below. The IC is housed in a 100 pin package (14 x 14 x 1.0mm) with a 7.6 x 7.6 mm exposed pad down.

The exposed pad is electrically shorted to the substrate pins GNDSUB1 and GNDSUB2. These three connection nodes are to be kept shorted on the application.

5 Overview and block diagram

The L9680 IC is an application specific standard component air bag system chip. Its main functions include, power management, deployment drivers, remote sensor interfaces (PSI-5 satellite sensors or active wheel speed sensors), diagnostics, deployment arming, hall-effect sensor interface, general purpose output drivers, watchdog timer, microcontroller failsafe input and control and a dedicated passenger airbag disarm signal. A block diagram for this IC is shown in *Figure 2*.

5.1 **Power supply**

- Integrated 1.882 MHz boost regulator, 33 V ± 5% or 23 V ± 5% nominal output
- Integrated 1.882 MHz boost regulator, 12 V/14.75 V nominal output, user selectable via SPI command
- Integrated 1.882 MHz synchronous buck regulator, 7.2 V/9 V \pm 4% nominal output, user selectable via SPI command
- Integrated 1.882 MHz synchronous buck regulator, 5 V \pm 3% or 3.3 V \pm 3% nominal output, user selectable via VCCSEL pin
- Over and under voltage detection and shutdown for all regulators
- Under-voltage lockout to guarantee buck regulator outputs disabled and discharged
- Integrated energy reserve capacitor fixed constant current source (65 mA, nominal) switch for controlled inrush and charge characteristics
- Integrated energy reserve diagnostics, capacitor value and ESR
- Integrated energy reserve crossover switch with current limit and battery input voltage monitoring
- Crossover switch 'active' output signal
- Integrated 25 V/20 V SPI selectable linear regulator for high side safing FET gate supply enabled via SPI or arming logic
- Reset output

5.2 Deployment drivers

- 12 high side deployment drivers, 12 low side deployment drivers
- User programmable deployment options
 - 1.20 A or 1.75 A minimum
 - programmable time in 0.1ms increments
- Capability to deploy a squib with a minimum current of 1.2 / 1.75 A and the SFx shorted to ground up to 25 V on SSxy
- Independently-controlled high-side and low-side FETs
- Squib resistance measurement
- Firing current monitor feature
- High and low side FET tests
- Open & shorts diagnostics, including between loop drivers
- Independent fire enable logic, SPI and discrete digital input

5.3 Remote sensor interfaces (4)

- Quad channel receiver, user selectable
 - standard PSI-5 v1.3 compatible with sync pulse or
 - active wheel speed sensors
- High side drivers for active wheel speed sensor mode (with driver protection)
- Current limit with short circuit protection diagnostics
- PSI-5 satellite sensor mode
 - Auto-adjusting current trip points for each satellite channel
 - Even parity, 8 or 10 bit messages, 125k or 189kbps
 - Satellite message error detection
- Active wheel speed sensor mode
 - Standard active dual level sensors, 7ma/14ma
 - Three level sensors with direction and air gap data, 7ma/14ma/28ma
 - PWM encoded two level sensor, 2 edges/tooth
 - PWM encoded two level sensor, 1 edge/tooth
 - Standard active two and three level sensor data decoding available through SPI

5.4 DC sensor interfaces (9)

- Nine integrated switch interfaces with current sense capability
- Compatible with Hall-effect, resistive and switch sensors
- Current limit protected
- System dedicated path to disable the passenger airbag with input from DC sensor interface

5.5 General purpose outputs (3)

- Three configurable high-side or low-side drivers
- ON-OFF mode and PWM 0-100% fine control
- Diagnostics for short circuit protection and open load detection
- Current limit and reverse battery protected

5.6 Arming logic

- User configurable safing algorithms with 16 safing records
- Four digital sensor interfaces through SPI
- Independent user programmable thresholds
- Independent user programmable latch timers
- Four discrete and independent arming logic outputs
- Four discrete and independent internal arming signals
- End-of-life interface

L9680

5.7 Other features

- One dedicated 32-bit SPI bus for global configuration and control
- One dedicated 32-bit SPI bus for remote sensor configuration and control
- Microcontroller 'state of health' input and control function
- Integrated watchdog control with 2 independent structures: windowed WD and algorithmic WD
- Temperature sensor
- Independent thermal shutdown protection on the ER boost switch, the SYNC boost switch, the energy reserve crossover switch, the energy reserve charge paths, the remote sensor interfaces and the general purpose outputs
- All diagnostics are digital and are available through SPI communications
- Configurable logic operation, 5 V or 3.3 V

6 Start-up and power control

6.1 Power supply overview

The L9680 IC contains a complete power management system able to provide all necessary voltages for a high feature airbag system or integrated safety system. A general block diagram is shown in *Figure 3*. The power supply block contains the following features:

- Two 3.3 V internal regulators for operating internal logic (CVDD) and analog circuits (VINT3V3). An external CVDD pin is used to provide filtering capacitance to digital section supply rail.
- Energy reserve supply (ERBOOST) achieved through an integrated 1.882 MHz switching boost regulator. The energy reserve capacitor is charged using an internal constant current source controllable through SPI. Besides, a second current source is available to discharge the capacitor. The primary function for the second current source is to diagnose the integrity of the energy reserve capacitor, value and ESR. During system shutdown, the device can enable the discharge current source via SPI command to quickly dissipate the remaining energy stored in the energy reserve capacitor.
- Sync pulse supply (SYNCBOOST) is achieved through an integrated 1.882 MHz switching boost regulator. The SYNCBOOST regulator ensures a minimum voltage is available for operating the satellite sync signal and also provides the input voltage to the remote sensor buck regulator. The sync pulse boost regulator is disabled for battery voltage levels resulting in an output voltage above the set regulation point.
- The integrated current limited ER switch requires no external components. This switch
 is controlled through the integrated power control state machine and is enabled either
 once a loss of battery is detected or a shutdown command is received. Under the same
 conditions also the discrete digital pin COVRACT is activated allowing the control of an
 external optional cross-over switch.
- Two 1.882MHz synchronous buck regulators for remote sensor supply and VCC. The SATBUCK regulator, remote sensor buck supply, is sourced from the SYNCBOOST regulator and can be selected to be either 7.2 V or 9 V nominal. The VCC regulator is sourced from the SATBUCK regulator and is user selectable through the VCCSEL pin to either 5 V or 3.3 V nominal voltage.
- Battery voltage sense input comparator with hysteresis and wake-up input are the primary control signals for the power supply control state machine.
- Based on own mission profile and ECU total current consumption, the user must evaluate if the activation of fast slope option of each ERBoost, SyncBoost and SatBuck regulator (bit 8/9/10, \$3F SW_REGS_CONF SPI register) is needed to increase the overall efficiency.

Figure 3. Power supply block diagram

6.2 Power mode control

Start-up and power down of the L9680 are controlled by the WAKEUP pin, VBATMON pin, VIN pin, device status and the SPI interface. There are four main power modes: power-off, sleep, active and passive mode.

Each power mode is described below and represented in the state flow diagram shown in *Figure 4*. The descriptions include references to conditions and sometimes nominal values. The absolute values for each condition are listed in the electrical specifications section.

6.2.1 POWER OFF mode

During the POWER-OFF Mode all supplies are disabled keeping the system in a quiescent state with very low current draw from battery. As soon as WAKEUP>WU_mon the IC will move to SLEEP Mode.

6.2.2 SLEEP mode

During the Sleep mode the VINT3V3 and CVDD internal regulators are turned on and the IC is ready for full activation of all the other supplies. As soon as VIN voltage is over a minimum threshold, all the other supplies are turned on and the IC enters the ACTIVE mode.

6.2.3 ACTIVE mode

This is the normal operating mode for the system.

All power supplies are enabled and the energy reserve boost converter starts to increase the voltage at ERBOOST. Likewise, the SYNCBOOST boost converter continues to charge and regulate to a nominal 12 V (default level at startup). Once the SYNCBOOST has reached a good value, the SATBUCK regulator starts up. In turn, when SATBUCK has ramped up, VCC regulator is enabled. Once the VCC buck regulator is in regulation, RESET is released allowing the system microcontroller and other components to begin their power-on sequence. Among these, also the ER charge current generator can be enabled by the microcontroller via a dedicated SPI command.

The active mode can be left when either WAKEUP pin or VIN voltage drop down. For the very first 9ms after having entered the active mode, the WAKEUP pin low would immediately cause the IC to switch back to sleep mode. After that time, WAKEUP pin low must be first confirmed by a μ C SPI_SLEEP command prior to cause the system to switch to passive mode. Passive mode is also entered in case of VIN voltage low.

6.2.4 PASSIVE mode

In this state, the reserve capacitor charge current and the ERBOOST boost converter are disabled. When in passive mode the device activates both the COVRACT output pin and the integrated ER switch to allow VIN to be connected to the ER capacitor. In this time, VIN is supposed to be increased up to almost VER level and the system operation relies on energy from the ER capacitor. Two scenarios are possible: high or low battery. If VIN < VINGOOD, the device moved from RUN state in ACTIVE mode to the ER state. Here, the ER capacitor is depleted while supplying all the regulators until the POR on internal regulator occurs. The threshold to decide the ER switch activation is based on VIN, because VIN is the supply voltage rail for ERBOOST regulator. If the device has still a good battery level, it entered the POWERMODE SHUTDOWN thanks to a microcontroller command to switch off. In this case, the VER node will be discharged down to approximately VIN level, which then will be supplied out of the battery line. System will continue to run up to a dedicated SPI command to disable the SATBUCK regulator, which will lead the device to enter the POWEROFF state.

The wake-up pin is filtered to suppress undesired state changes resulting from transients or glitches. Typical conditions are shown in the chart below and summarized by state.

Figure 5. Wake-up input signal behaviour

Condition summary:

- 1. No change of sleep mode state but current consumption may exceed specification for sleep mode.
- 2. The sleep mode current returns to within specified limits.
- 3. Power supply exits sleep mode. Switchers start operating if applicable voltages exceed under voltage lockouts. As T_{wakeup} timeout is not elapsed, a low level at WAKEUP instantaneously sends the system back to sleep.
- 4. Sleep reset is released and the entire system starts operating. An SPI command to enter sleep state would not be executed.
- 5. No change in system status, an SPI command to turn off switchers would be ignored.
- 6. No change in system status, but an SPI command to turn off switchers would be accepted and turn the system off.

With the below table, all the functionalities of the device are shown with respect of the power states. When one function is flagged, the related circuitry cannot be activated on that state.

| | Power MODE | | | | | | | |
|--------------------------|--------------|-------------------|-------|---------|-----|------------------------|----|---------------------|

6.2.5 Power-up and power-down sequences

The behaviour of the IC during normal power-up and power-down is shown in *Figure 6* to *Figure 10*. The following sequences represent just a subset of all possible power-up and power-down scenarios. In *Figure 6* a normal IC power-up controlled by the state of the WAKEUP pin is shown assuming the VCOREMON function activated, while in *Figure 7* assuming the VCOREMON function disabled.

6.2.6 IC operating states

Different states can be identified while operating the device. These states allow safe and predictable initialization, test, operation and final disposal of the part (scrapping).

As soon as the RESET signal is de-asserted at the beginning of the ACTIVE mode, the microcontroller powers up. At this stage, L9680 is in the Init state: during this state the device must be initialized by the controller. In particular, the watchdog timer window can be programmed during this state.

When the watchdog service begins (upon the first successful watchdog feed), the device switches to Diag state for diagnostics purposes. The remaining configuration of the device is allowed in this state, in particular for safing records and deployment masks. Several tests are also enabled while in this state and all these tests are mutually exclusive to one another. HS and LS switch tests of the squib drivers can only be processed during this Diag state. Also high side safing FET can only be run during this state. When not in Diag state, any commands for squib driver switch tests will be ignored. Other checks are also performed: on the arming outputs to check for non-stuck-at conditions on the pins and on the configured firing time configuration through one of the ARMx pin. The SSM remains in this state until commanded to transition into the Safing state or Scrap state via the dedicated SPI commands.

Upon reception of the SAFING_STATE command while in Diag state, the device enters Safing state. This is the primary run-time state for normal operation, and the logic performs the safing function, including monitoring of sensor data and setting of the ARMx signals. The only means of exiting Safing state is by the assertion of the SSM_Reset signal.

The Scrap state is entered upon reception of the SCRAP_STATE command while in Diag state. While in Scrap state, the part allows the main microcontroller to initiate a transition to Arming state, and monitoring of the Remote Sensor SPI interface and the safing logic is disabled. From Scrap state, the device can transition to Arming state only, and the only means of moving back to Init state is through an SSM_Reset.

In order to protect from inadvertent entry into Arming state, and to prevent undesired activation of the safing signals, a handshake mechanism is used to control entry into, and exit from Arming state. This handshake is described further in Section 11.6. While in Arming state, the arming outputs are asserted. Exit from Arming state occurs when the periodic SCRAP_KEY commands cease (timeout), the key value is incorrect, or when SSM_Reset is asserted. Upon exit, the device re-enters Scrap state, except for the case of SSM_Reset, which results in entry into Init state.

The device operating states are shown in *Figure 11*.

Figure 11. IC operating state diagram

6.3 ERBOOST switching regulator

The L9680 IC uses an advanced energy reserve switching regulator operating at 1.882MHz nominal. The higher switching frequency enables the user to select smaller less expensive inductors and moves the operating frequency to permit easier compliance with system emissions.

The ERBoost switching regulator uses a classical peak current mode control loop to properly regulate the output voltage and includes an over-voltage protection that immediately switch off the PowerMOS to protect the device. The regulator includes also a soft start circuit which apply a ramp on the over current threshold from the 40% of IOC_ERBST value to the maximum one with 16 steps and within 1024 µs. The soft start is restarted every time the regulator has a transition from the ER_BST_OFF to the ER_BST_ON state.

The energy reserve boost regulator charges the external system tank capacitor through an integrated fixed current source significantly reducing in-rush currents typical of large energy reserve capacitors. The boost circuit provides energy for the reserve capacitor with assumed run time load of less than 20 mA and to the VSF regulator. Once system shutdown is initiated or a loss of battery condition is diagnosed, the boost regulator is by default disabled so that system power can be taken from the energy reserve capacitor. Alternatively, the ER Boost could be kept on even during the ER State by setting the SYS_CFG(KEEP_ER_BOOST_ON) bit.

The energy reserve boost regulator defaults to 23 V at power-on and can be set to 33 V nominal by the user through an SPI command. The boost converter can also be disabled by the user through an SPI command. Enabling, disabling and setting the boost output voltage

is done through the System Control (SYS_CTL) register. Boost converter diagnostics include over voltage and under voltage and the circuit is fully protected against shorts. Boost fault status is available through the SPI in Fault Status Register (FLTSR). The integrated FET featuring the boost switch is protected against short to battery by means of a thermal shutdown circuit. When thermal fault is detected the FET is switched off and latched in this state until the related fault flag ERBST_OT in the FLTSR register is read. In case of loss of BSTGND ground the FET is not turned on. Loss of ground can be detected also when the FET is off thanks to a pull-up current present on the BSTGND pin. The FET will be automatically reactivated as soon as ground connection is restored. Over-voltage protection from load dump and inductive flyback is provided via an active clamp and an ER_Boost disable circuitry, see *Figure 12*.

Normal run time power for the system is provided directly from the battery input, not from the boost. Boost energy is available to the system through the energy reserve crossover switch once battery is lost or a commanded system shutdown is initiated.

6.4 Energy reserve capacitor charging and discharging circuits

The energy reserve capacitor connected to VER pin can be charged in an efficient way by means of a current generator. Its capability is 65 mA nominal, so that for example a 10 mF capacitor can be charged in approximately 4 s to 24 V. The current generator is activated or deactivated by SPI command only while in ACTIVE mode. When not in ACTIVE mode, the generator is always switched off in order to decouple ERBOOST node voltage from VER reserve voltage.

L9680 also offers a safe control to discharge the ER capacitor by means of a fixed current generator. This discharge can be controlled via SPI command while not in SLEEP mode. Furthermore, this discharge circuit is mutually exclusive with the ER charging circuit, to avoid inefficient way of controlling the charge on the VER energy reserve capacitor.

6.5 **ER CAP diagnostic**

The L9680 IC contains a full integrated solution to check the connection, value and series resistance of energy reserve capacitor independent from ER Cap leakage current and Boost Voltage level.

6.5.1 ER CAP measurement

The IC contains two current generators used to charge and discharge the energy reserve capacitor connected on ER pin. The simplified block diagram is shown in the figure below.

Figure 16. ER CAP measurement block diagram

To obtain an accurate ER CAP measurement, the VER voltage conversion must be required when both current generators are off, namely no current flows through ER cap permits to avoid ESR error contribution.

DS11615 Rev 2

The user can decide the charge and discharge time based on the ER CAP used in application, in order to maximize the differential voltage and then improve the accuracy.

Anyway, a timeout on ER Discharge current has been implemented to prevent thermal issue, so the discharge time cannot be longer than 350 ms.

Figure 17. ER CAP measurement timing diagram

The following formulas can be used to retrieve the ER CAP value from the voltage and timing measurements.

$$\Delta V_1 + \Delta V_2 = \frac{I_1 + I_{LEAK}}{C} T_1 + \frac{I_2 - I_{LEAK}}{C} T_2$$
$$C = \frac{2 \cdot I \cdot T}{V_{start} + V_{end} - 2 \cdot V_{stop}}$$

T₁ = discharge time

 T_2 = charge time, same as discharge time

$$T_{1} = T_{2} = T$$

$$\Delta V_{1} = V_{start} - V_{stop}$$

$$\Delta V_{2} = V_{end} - V_{stop}$$

$$I_{1} = discharge current$$

 I_2 = charge current, same as discharge current

$$|I_1 = |I_2 = |$$

I_{LEAK} = leakage current

6.5.2 ER CAP ESR measurement

The IC contains the capability to perform a measurement of the equivalent series resistance of energy reserve capacitor. In this case the discharge current is 10 times higher to create a voltage difference proportional to the ER CAP ESR. The voltage measurement and conversion is automatically executed once the user requires the ESR measurement through the LPDIAGREQ register.

Upon an ESR measurement is requested, the IC executes an internal automatic sequence to take three voltage measurements at the ER node, toggling the ER discharge current source on and off as shown in *Figure 19*. The test lasts for T_{ESR_DIAG}. After this time has elapsed, the results can be retrieved by reading the DIAGCTRL_x registers. The three ER voltage measurements are provided at the same time in DIAGCTRLA, DIAGCTRLB and DIAGCTRLC registers. During the execution of the ESR measurement no other activity on ADC is allowed. The user must ensure no other ADC requests are queued to be executed at the same time of ESR measurement. The ESR diagnostic, once initiated, will continue without interruption even if the device enters in ER State because of a battery loss event.

 $\mathbf{\nabla}$

Figure 19. ER ESR measurement timing diagram

The ER CAP ESR can be calculated according to the following formula:

$$\mathsf{ESR}_{\mathsf{ERCAP}} = \frac{\mathsf{V}_{\mathsf{C}} - \mathsf{V}_{\mathsf{B}}}{\mathsf{G}_{\mathsf{ER}_\mathsf{ESR}} \cdot \mathsf{I}_{\mathsf{ER}_\mathsf{DISCHARGE_HIGH}}} + \mathsf{OFF}_{\mathsf{ER}_\mathsf{ESR}}$$

6.6 ER switch and COVRACT pin

L9680 allows the system to run out of the reserve capacitor energy stored on VER node by means of the charging boost regulator. In this way, an extended operation can take place even in case of battery lost. The ER switch implements a connection from the VER pin to the VIN node, supply input for the SYNCBOOST regulator and for internal power supplies.

The ER switch is automatically activated upon entering the PASSIVE mode. Voltage difference between VIN and VER is monitored in order to prevent VER back-feeding when VIN exceeds VER by $V_{\text{ER}_{SW}_{OV}_{TH}}$. The ER switch is automatically deactivated upon the above mentioned overvoltage detection.

During PASSIVE mode the discrete digital output pin COVRACT is activated to allow for external optional cross-over switch control (except during VINGOOD blanking state, where the COVRACT is deactivated).

Figure 20. ER switch state diagram

6.7 SYNCBOOST boost regulator

The SYNCBOOST boost regulator also operates at 1.882 MHz allowing the user to select smaller less expensive external components. The regulator provides a 12 V/14.75 V nominal for the sync pulse feature used in PSI-5 bussed satellite sensor configuration. The regulator also provides the power for the SATBUCK regulator.

The SyncBoost switching regulator uses a classical peak current mode control loop to properly regulate the output voltage and includes an over-voltage protection that immediately switch off the PowerMOS to protect the device. The regulator includes also a soft start circuit which apply a ramp on the over current threshold from the 40% of $I_{OC\ SYNCBST}$ value to the maximum one with 16 steps and within 1024 $\mu s.$ The soft start is restarted every time the regulator is enabled, namely there is a transition from the SYNCBOOST OFF state to the SYNCBOOST ON state.

In normal operation, the SYNCBOOST regulator operates directly from battery providing a voltage level to operate the sync pulse driver circuit. Should the input voltage be greater than regulation point, the output voltage will track the input voltage less any drops in the external components.

The boost regulator is enabled automatically by the power control state machine, but can be disabled on purpose via SPI command through the SYS CTL(SYNCBST EN) bit. The regulation point is fixed at a nominal 12 V at startup. User may increase the output regulation voltage to 14.75 V nominal by setting the SATV bit via a dedicated SPI command, should an extended voltage range be needed.

Boost converter diagnostics include over voltage and under voltage, reported by the S BST NOK bit in the POWER STATE register, and the circuit is fully protected against shorts. The integrated FET featuring the boost switch is protected against short to battery by means of a thermal shutdown circuit. When thermal fault is detected the FET is switched off and latched in this state until the related fault flag ERBST OT in the FLTSR register is read.

In case of loss of ground the FET is not turned on. Loss of ground can be detected also when the FET is off thanks to a pull-up current present on the BSTGND pin. The FET will be automatically reactivated as soon as ground connection is restored. Over-voltage protection from load dump and inductive flyback is provided via an active clamp and a SYNC_Boost disable circuitry, see *Figure 21*.

DS11615 Rev 2

6.8 SATBUCK regulator

The SATBUCK regulator provides a nominal 7.2 V regulated output voltage at startup for the remote satellite and wheel speed interface circuitry and the VCC buck regulator. The buck regulator is enabled automatically by the power control state machine. This regulator is protected against short circuits. Should the user need a higher voltage range for the remote sensor interface, a specific SPI command allows the output voltage to be increased at 9 V nominal by setting the SAT_V bit. Fault status is available through SPI in the Fault Status Register (FLTSR). The buck converter operates at 1.882 MHz allowing the user to select smaller less expensive external components. Moreover, the synchronous buck regulator integrates the external recirculation diode.

6.9 VCC buck regulator

The VCC buck regulator also operates at 1.882 MHz and is user selectable to either 3.3 V or 5 V nominal output voltage. The user can select the output voltage through the VCCSEL pin. To select 5 V operation, the user must bias VCCSEL to a level higher than V_{TH2 H VCCSEI} for instance SyncBoost. For 3.3 V operation, the VCCSEL pin must be biased to a level lower than V_{TH2 L VCCSEL}. An internal weak pull down is connected to VCCSEL to ensure the input remains at ground potential in case of open pin. The internal power control state machine will read the VCCSEL input pin and latch the resulting state upon the SATBUCK voltage reaches the good value (SATBUCK_OK = 1). Upon latching the VCCSEL state, the VCC buck regulator cannot be changed by the user.

The VCC regulator has over and under voltage detections and shutdown capability and it is also protected against short circuits. During start-up an internal pull up current is enabled in order to detect a potential VCC pin open fault trough the over voltage detection. This pull up current is disabled once in VCC_ON or VCC_SHUTDOWN states. During normal operation, VCC_ON state, the VCC pin open fault is quickly detected through the Under Voltage Detection Low to prevent any MCU damage.

An open VCC pin shall lead to an under voltage condition on VCC supply monitor. The SPI related signals (SCLK, MISO, MOSI, CS) or other digital nets shall not power the VCC pin due to back-feeding paths.

57

6.10 VCOREMON external core voltage monitor

The device includes the possibility to monitor the external core voltage of MCU in case an additional external regulator is used to provide the 1.2V rail. The internal power control state machine will read the VCCSEL input pin and latch the resulting state upon the VCCBUCK regulator enters in the VCC_ON state: if VCCSEL is lower than $V_{TH1_L_VCCSEL}$ the VCORE monitor will be enabled, otherwise, if VCCSEL is higher than $V_{TH1_H_VCCSEL}$, the VCORE monitor will be disabled.

In summary:

- VCCSEL < V_{TH1_L_VCCSEL} (VCCSEL shorted to ground), to select VCC = 3.3 V and to enable the VCORE monitor
- V_{TH1_H_VCCSEL} < VCCSEL < V_{TH2_L_VCCSEL} (VCCSEL shorted to VCC), to select VCC = 3.3 V and to disable the VCORE monitor.
- VCCSEL > V_{TH2_H_VCCSEL} (VCCSEL shorted to SYNCBOOST), to select VCC = 5 V and to disable the VCORE monitor.

The VCORE monitor is enabled once the VCC regulator is in VCC_ON state, therefore the external MCU core voltage regulator (1.2 V) must reach the regulation within 4ms after the VCC regulator power-up.

Upon latching the VCCSEL state, the VCOREMON activation cannot be changed by the user.

In case of VCCSEL open pin, an internal pull down current would force VCCSEL to ground and then the VCORE monitor will be enabled function.

If the VCORE voltage is low and the VCCSEL pin is higher than $V_{TH1_L_VCCSEL}$, after the 4ms delay from power-up, a latched VCOREMON fault will cause RESET to drive low, even though VCCSEL pin is high enough to satisfy the disabling of VCOREMON function. This occurs only once at power-up, and is then appropriately disabled. For this reason the RESET is released 500 µs (namely the reset_hold_time) after the 4 ms delay from power-up as showed in *Figure 6*.

6.11 VSF regulator and control

The L9680 provides a low current linear regulator that can be used in the system design to bias the external high side safing switch. The regulator output is 20 V nominal (configurable to 25 V via SPI command). VSF is enabled if any of the ARMxINT signal is asserted, as shown in *Figure 25*. The VSF regulator supply input is ERBOOST.

VSF voltage can be monitored by the user through the internal ADC. Characteristics for this function are shown in the electrical performance tables.

6.12 Oscillators

The device integrates two trimmed oscillators, both of them with spread spectrum capability selectable via the CLK_CNF register.

The main oscillator runs at 16 MHz typ and is used to provide clock to the internal synchronous logic. Moreover, this frequency is divided down by factor 8.5 to generate clocks for the switching regulators (1.882 MHz typ).

The auxiliary oscillator runs at 7.5 MHz typ and is used to monitor the main oscillator. In case the main oscillator frequency was lower than $f_{OSC_LOW_TH}$ threshold or higher than $f_{OSC_HIGH_TH}$ threshold, the condition is detected by the frequency monitor circuit and then latched into the CLKFRERR flag in the FLTSR register and a POR is issued.

6.13 Reset control

The device provides reset logic to safely control system operation in the event of internal ECU failures. Several internal reset signals are generated depending on the type of failure detected. In *Figure 26* the voltage monitoring diagram is shown.

Figure 26. Internal voltage monitors

An active low pin output (RESET pin) is driven from the L9680 to allow resetting of external devices such as the microcontroller, sensors, and other ICs within the ECU.

Three internal reset signals are generated by the device:

• POR

Power On Reset - This reset is asserted when a failure is detected in the internal supplies or bandgap circuits. When active, all other resets are asserted.

WSM_RESET

Watchdog State Machine Reset - This reset is generated when the POR is active or when a failure is detected in the VCC or VCORE supply.

SSM_RESET

System State Machine Reset - This reset is asserted when the POR or the WSM_RESET are active, or when a failure is detected in either Watchdog state machine, or again when the MCUFAULTB pin is active.

The RESET pin is the active-low signal driven on the output pin, and is an inverted form of SSM_RESET.

The cause of the RESET activation is latched and reported into the Fault Status Register FLTSR and cleared upon SPI reading.

The reset generated by the MCUFLT_ERR can be masked by the MCU_FLT_TEST test mode signal. This allows verification of MCUFLT pin operation and, in turn, microcontroller fault conditions without asserting a reset. The MCURST bit is still set whether in test mode or not.

The reset logic shall be controlled as shown in the diagram below:

Figure 27. Reset control logic

7 SPI interfaces

The L9680 system solution device has many user selectable features controlled through serial communications by the integrated microcontroller. The device features two SPI interfaces: one global SPI and one Remote Sensor SPI. The global SPI interface provides general configuration, control and status functions for the device, while the Remote Sensor SPI provides dedicated access to Remote Sensor Data and Status Registers.

7.1 SPI protocol

Each SPI interface (Global and Remote Sensor) use their own dedicated set of 4 I/O pins: CS_G, SCLK_G, MOSI_G and MISO_G for Global SPI; CS_RS, SCLK_RS, MOSI_RS and MISO_RS for Remote Sensor SPI. Both the SPI interfaces use the same protocol described here below (the suffix '_X' used in the SPI pin names below is intended to stand for either '_G' or '_RS' depending on the particular SPI interface considered)

The IC SPI interface is composed by an input shift register, an output shift register and four control signals. MOSI_X is the data input to the input shift register. MISO_X is the data output from the output shift register. SCLK_X is the clock input used to shift data into the input shift register or out from the output one while CS_X is the active low chip select input.

All SPI communications are executed in exact 32 bit increments. The general format of the 32 bit transmission for the SPI interface is shown in *Table 5*.

Data sent to the IC (i.e. MOSI_X) consists of a target read register ID (RID), a target write register ID (WID), write data parity (WPAR) and 16 bits of data (WRITE). WRITE data is the data to be written to the target write register indicated by WID. Data returned from the IC (i.e. MISO_X) consists of a global status word (GSW), read data parity (RPAR) and 20 bits of data (READ). READ data will be the contents of the target read register as indicated by the RID bits. The parity bits WPAR and RPAR cover all the 32 bits of the MOSI and MISO frames, respectively. Odd parity type is used.

| | SPI register R/W | | | | | | | | | | | | | | | |

| SPI_MISO | READ[15:0] | | | | | | | | | | | | | | | |

Table 5. SPI MOSI and MISO frames layout

The communications is controlled through CS_X, enabling and disabling communication. When CS_X is at logic high, all SPI communication I/O is tri-stated and no data is accepted. When CS_X is low, data is latched on the rising edge of SCLK_X and data is shifted on the falling edge. The MOSI_X pin receives serial data from the master with MSB first. Likewise for MISO_X, data is read MSB first, LSB last.

The L9680 contains a data validation method through the SCLK_X input to keep transmissions with not exactly 32 bits from being written to the device. The SCLK_X input counts the number of received clocks and should the clock counter exceed or count fewer

than 32 clocks, the received message is discarded and a SPI_FLT bit is flagged in the Global Status Word (GSW). The SPI_FLT bit is also set in case of parity error detected on the MOSI_X frame. Any attempt to access to a register with forbidden access mode (read or write) is not leading to changes to the internal registers but the SPI_FLT bit is not set in this case.

7.2 Global SPI register map

The Global SPI interface consists of several 32-bit registers to allow for configuration, control and status of the IC as well as special manufacturing test modes. The register definition is defined by the read register ID (RID) and the write register ID (WID) as shown in *Table 6*. Global ID bit (GID) is used to extend available register addresses, but it is shared between RID and WID; only RID and WID with the same GID value can be addressed within the same SPI word. The operating states here show in which states the SPI command is processed.

The L9680 checks the validity of the received WID and RID fields in the MOSI_G frame. Should a SPI write command with WID matching a writable register be received in an illegal operating state, the command will be discarded and the ERR_WID bit will be flagged in the next Global Status Word GSW. The ERR_WID flag is not set in case WID is addressing a read/only register. Should a SPI read command be received containing an unused RID address, the command will be discarded and the ERR_RID bit will be flagged in the current GSW.

1. A check mark indicates in which operating state a WRITE-command is valid.

2. KEEP_ERBOOST_ON, LOW_POWER_MODE, VSF_V and VINGOOD_FILT_SEL bits are writable in all states, the other bits of SYS_CFG are only writable in INIT state.

66/280

7.3 Global SPI tables

A summary of all the registers contained within the global SPI map are shown below and are referenced throughout the specification as they apply. The SPI register tables also specify the effect of the internal reset signals assertion on each bit field (the symbol '-' is used to indicate that the register is not affected by the relevant reset signal').

Global SPI global status word

The Global SPI of L9680 contains an 11-bit word that returns global status information. The Global Status Word (GSW) of the Global SPI is the most significant 11 bits of MISO_G data.

| MISO_G | GSW | Name | POR | WSM | SSM | Description |
|--------|-----|----------|-----|-----|-----|--|
| 31 | 10 | SPIFLT | 0 | 0 | 0 | SPI Fault, set if previous SPI frame had wrong parity check or wrong number of bits, cleared upon read 0 No fault 1 Fault |
| 30 | 9 | DEPOK | 0 | 0 | 0 | General Deployment Successful Flag, logical OR of the corresponding CHxDS bits (bit 15) in DSRx Registers 0 All the DSRx-CHDS bits are 0 1 At least one of the DSRx-CHDS bits is 1 |
| 29 | 8 | 0 | 0 | 0 | 0 | Unused |
| 28 | 7 | WDT/TM_S | 0 | 0 | 0 | State of WDT/TM pin 0 WDT/TM=0 1 WDT/TM=1 |
| 27 | 6 | ERSTATE | 0 | 0 | 0 | Set when Powermode state machine is in ER state 0 Powermode state machine is not in ER state 1 Powermode state machine is in ER state |
| 26 | 5 | POWERFLT | 0 | 0 | 0 | Fault present in Power State Register, logical OR between bits from 18 to 9 of POWER_STATE Register 0 All the bits from 18 to 9 in the POWER_STATE Registers are 0s 1 At least one of the bits from 18 to 9 in the POWER_STATE Registers is 1 |
| 25 | 4 | FLT | 1 | 1 | 1 | Fault present in Fault Status Register (FLTSR), logical OR between all bits of FLTSR 0 All the bits in the Fault Status Register (FLTSR) are 0s 1 At least one of the bits in the Fault Status Register (FLTSR) is 1 |
| 24 | 3 | CONVRDY2 | 0 | 0 | 0 | ADC Conversion of request C or D has been completed so new results are available 0 No new data available 1 New data available |
| 23 | 2 | CONVRDY1 | 0 | 0 | 0 | ADC Conversion of request A or B has been completed so new results are available 0 No new data available 1 New data available |

7.4 Remote sensor SPI register map

The Remote Sensor SPI interface consists of twelve 32-bit read registers (one for each logical channel) to allow for access to decoded sensor data and fault registers. The registers are addressed by the read register ID and the Global ID bit.

The L9680 checks the validity of the received RID field in the MOSI_RS frame. Should a SPI read command be received containing an unused RID address, the command will be discarded and the ERR_RID bit will be flagged in the current GSW.

| GID RID / WID | | Have | R/W | Norma | Description | Operating State | | | | | | | | | | |

7.5 Remote sensor SPI tables

A summary of all the registers contained within the remote sensor SPI map are shown below and are referenced throughout the specification as they apply. The SPI register tables also specify the effect of the internal reset signals assertion on each bit field (the symbol '-'is used to indicate that the register is not affected by the relevant reset signal').

7.5.1 Remote sensor SPI global status word

The Remote Sensor SPI of L9680 contains an 11-bit word that returns global status information. The Global Status Word (GSW) of the Remote Sensor SPI is the most significant 11 bits of MISO_RS data.

| MISO_RS | GSW | Name | POR | WSM | SSM | Description |
|---------|------------|--------|-----|-----|-----|---|
| | | | | _ | | SPI Fault, set if previous SPI frame had wrong parity check or wrong number of bits, cleared upon read ' |
| 31 | 10 | SPIFLT | 0 | 0 | 0 | 0 No fault |
| | | | | | | 1 Fault |
| 30 | 9 | 0 | 0 | 0 | 0 | Unused |
| | | | | | | Remote Sensor Interface Fault Present, logical OR of the corresponding FLTBIT bits (bit 15) for all faults but NODATA |
| 29 | 29 8 RSFLT | | 0 | 0 | 0 | 0 All the RSDRx-FLTBIT bits are 0 |
| | | | | | | 1 At least one of the RSDRx-FLTBIT bits is 1 and the associated fault code is different from NODATA |
| 28 | 7 | 0 | 0 | 0 | 0 | Unused |
| 27 | 6 | 0 | 0 | 0 | 0 | Unused |
| 26 | 5 | 0 | 0 | 0 | 0 | Unused |
| 25 | 4 | 0 | 0 | 0 | 0 | Unused |
| 24 | 3 | 0 | 0 | 0 | 0 | Unused |
| 23 | 2 | 0 | 0 | 0 | 0 | Unused |
| 22 | 1 | 0 | 0 | 0 | 0 | Unused |
| | | ERR_RI | | | | Read address received in the actual SPI frame is unused so data in the response is don't care |
| 21 | 0 | D | 0 | 0 | 0 | 0 No Error |
| | | | | | | 1 Error |

8 Deployment drivers

The squib deployment block consists of 12 independent high side drivers and 12 independent low side drivers. Squib deployment logic requires a deploy command received through SPI communications and either an arming condition processed by safing logic or a proper ARMx input pin assessment, depending on whether the internal safing engine is used or not. Both conditions must exist in order for the deployment to occur. Once a deployment is initiated, it can only be terminated by an SSM_RESET event.

L9680 allows all 12 squib loops to be deployed at the very same time or in other possible timing sequence. Deployment drivers are capable of granting a successful deployment also in case of short to ground on low-side circuit (SRx pins). Firing voltage capability across high side circuit is maximum 25 V. High side and low side drivers account for a maximum series total resistance of 2 Ω . Each loop is granted for a minimum number of deployments of 50, under all normal operating conditions and with a deployment repetition time higher than 10s. Both the High and the Low side FET drivers are equipped with passive gate turn-off circuitries to guarantee the FETs are kept in off state also when the device is unpowered or during power-up/down transients.

8.1 Control logic

A block diagram representing the deployment driver logic is shown below. Deployment driver logic features include:

- Deploy command logic
- Deployment current selection
- Deployment current monitoring and deploy success feedback
- Diagnostic control and feedback

162/280

Figure 29. Deployment driver control logic - Enable signal

DS11615 Rev 2

The high level block diagram for the deployment drivers is shown below:

8.1.1 Deployment current selection

Deployment current is programmed for each channel using the Deploy Configuration Register (DCRx) shown in *Section* 7.3.7.

The deploy time selection allows the device to deploy for a time up to 4.032 ms. Careful considerations should be done in order to avoid damage on the squib driver section for excessive thermal heat. In order to prevent device damage, it is suggested to avoid excessive voltage drop between SSxy and SFxy. In case the 1.75 A deployment current level is selected, the voltage drop across the pins should be limited to maximum 17 V for deployment times longer than 0.7 ms and up to 2 ms and 15 V up to 3.2 ms. In case 1.2 A is selected, the voltage drop should be limited to maximum 22 V for deployment times longer than 2 ms and up to 3.2 ms.

8.1.2 Deploy command expiration timer

Deploy commands are received for all channels using SPI communications. Once a deploy command is received, it will remain valid for a specified time period selected in the *Deployment configuration registers (DCR_x)*. The deploy status and deploy expiration timer can be read through the *Deployment status registers (DSR_x)*. The deploy expiration timer is selectable via 2 bits and the maximum programmable time is 500 ms nominal.

DS11615 Rev 2

8.1.3 Deployment control flow

Deployment control logic requires the following conditions to be true to successfully operate a deployment:

- POR = 0
- SSM to be either in Safing State or Arming State
- a valid arming condition processed by safing logic or ARMx signals to be set (depending on selection of internal or external safing engine)
- channel-specific deploy command request bits to be set via SPI in the Deploy command Register (DEPCOM)
- a global deployment state has to be active, as described in the following figure.

Figure 32. Global SPI deployment enable state diagram

In case a multiple deployment request would be needed, i.e. deploying the same channel in sequence, a toggle on DEP_DISABLED has to be performed and a new DEPCOM command on the same channel has to be sent.

The SPI DEPCOM command is ignored if the device is in the DEP_DISABLED state and the deploy command is not set. While in DEP_ENABLED state, the following functionalities that could be active are forced to their reset state:

- All squib and DC sensor diagnostic current or voltage sources
- All squib, DC sensor and ADC diagnostic MUX settings, state machine, etc.

The SPI_LOCK and SPI_UNLOCK signals are available in the SPIDEPEN command:

High-side and Low-side enablers (ARMx) are assigned to the desired channels by means of the programmable loop matrix. Loop matrix registers are 4, one for each ARMx signals. In each loop matrix register 12 bits are present to associate independently loops with ARMx signals. In case external safing is selected LOOP_MATRIX_ARM4 register is don't care because ARM4 pin is used to arm the low side of all loops without association matrix. Deploy commands in the Deploy Command Register (DEPCOM) are channel specific.

Deployment requires a valid arming condition from safing logic or ARMx signals to be set any time before, during or after the specific sequence of deploy commands is received. It is feasible for a deploy command to be received without a valid arming condition from safing logic or the ARMx being set. In this case, the deploy command will be terminated according

to the *Deploy command expiration timer*. Likewise, a valid arming condition signal can be set without receiving a Deploy Command. In this case, the enabling signals will remain active according to the Arming Enable Pulse Stretch Timer or the ARMx enabling state. The Arming Enable Pulse Stretch Timers is available in the AEPSTS register.

8.1.4 Deployment current monitoring

A current comparator is used to indicate when the output current from the HSD, SFx, exceeds the deployment current threshold, I_{THDEPL}. The timer signal remains active and increments while the current meets the programmed deploy current as set in the Deploy Configuration Register. The deploy current counter value is stored in the Deploy Current Monitor Timer Register XY (DCMTSxy). There is a unique timer register for each channel.

If the deploy current falls below the specified current threshold momentarily and recovers, the deploy current counter will pause during the drop-out and continue once the current exceeds the threshold. The deploy current counter will not be reset by the presence or absence of current in the deployment channel.

Figure 33. Current monitor counter behavior

The deploy current counter is reset to \$0000 as soon as a toggle on DEP_DISABLED is performed and a new DEPCOM command on the same channel is received.

8.1.5 Deployment success

Deploy success flag is set when the deploy timer elapses. This bit (CHxDS) is contained in the Deploy Status Register. Within the Global Status Word register (GSW), a single bit (DEPOK) is also set once any of the 12 deployment channels sets a deploy success flag.

8.2 Energy reserve - deployment voltage

One deployment voltage source pin is used for adjacent channels (e.g. SS23 for channels 2 and 3). These pins are directly connected to the high side drivers for each channel.

8.3 Deployment ground return

L9680 is hosted in a particular frame allowing squib driver ground feedback to be connected to an internal ground ring. This ring is electrically connected to the package exposed pad and to the GNDSUB1 and GNDSUB2 pins. Connection to these two pins is made by means of a strong metal layer, therefore this connection is sufficient for all deployments occurring

DS11615 Rev 2

simultaneously, even in case of only one out of the three possible connections being available.

8.4 Deployment driver protections

8.4.1 Delayed low-side deactivation

To control voltage spikes at the squib pins during drivers deactivation at the end of a deployment, the low side driver is switched off after t_{depl_ls-dly} delay time with respect to the high side deactivation.

8.4.2 Low-side voltage clamp

The Low side driver is protected against overvoltage at the SRx pins by means of a clamping structure as shown in *Figure 31*. When the Low side driver is turned off, voltage transients at the SRx pin may be caused by squib inductance. In this case a low side FET drain to gate clamp will reactivate the low side FET allowing for residual inductance current recirculation, thus preventing potential low side FET damage by overvoltage.

8.4.3 Short to battery

The Low side driver is equipped with current limitation and overcurrent protection circuitry. In case of short to battery at the squib pins, the short circuit current is limited by the Low side driver to I_{LIMSRx} . If this condition lasts for longer than t_{LIM} deglitch filter time then the low and high-side drivers will be switched off and latched in this state until a new deployment is commanded after SPI_DEPEN is re-triggered.

8.4.4 Short to ground

The squib driver is designed to stand a short to ground at the squib pins during deployment. In particular, the current flowing through the short circuit is limited by the high side driver (deployment current) and the high-side FET is sized to handle the related energy.

In case the short to ground during deployment occurs after an open circuit, a protection against damage is also available. The high side current regulator would have normally reacted to the open circuit by increasing the Vgs of the high side FET. Thanks to a dedicated fast comparator detecting the open condition, the driver is able to discharge the FET gate quickly in order to reduce current overshoot and prevent potential driver damage when the short to ground occurs.

8.4.5 Intermittent open squib

A dedicated protection is also available in case of intermittent open load during deployment. In this case, if load is restored after an open circuit, due to slow reaction of the high-side current regulation loop, the current through the squib is limited only to I_{LIMSRx} by the low side driver. If this condition lasts for longer than t_{LIMOS} then the high side is turned off for $t_{HSOFFOS}$ and then reactivated. By this feature, intermittent open squib and short to battery faults may be distinguished and handled properly by the drivers.

8.5 Diagnostics

The L9680 provides the following diagnostic feedback for all deployment channels:

- High voltage leakage test for oxide isolation check on SFx and SRx
- Leakage to battery and ground on both SFx and SRx pins with or without a squib
- Short between loops diagnostics
- Squib resistance measurement with leakage cancellation and selectable range (10/50 Ω)
- High squib resistance with range from 500 Ω to 2000 Ω
- SSxy, SFx and VER voltage status
- High and Low side FET diagnostics
- High side driver diagnostics
- Loss of ground return diagnostics
- High Side Safing FET diagnostics

The above diagnostic results are processed through a 10 bit Analog to digital algorithmic converter. These tests can be addressed in two different ways, with a high level approach or a low-level one. The main difference between the two approaches is that with the low level approach the user is allowed to precisely control the diagnostic circuitry, also deciding the proper timings involved in the different tests. On the other hand, the high level approach is an automatic way of getting diagnostic results for which an internal state machine is taking care of instructions and timings.

The following is block diagram of the Squib Diagnostics.

Figure 34. Deployment loop diagnostics

The leakage diagnostic includes short to battery, short to ground and shorts between loops. The test is applied to each SFx and SRx pin so shorts can be detected regardless of the resistance between the squib pins.

8.5.1 Low level diagnostic approach

In this approach, each of the test steps described in the sections below requires user intervention by issuing the proper SPI command.

High voltage leakage test for oxide isolation check

This test is mandatory to address possible leakages that could not be experienced at low voltages on SFx or SRx pins. The I_{source} current generator (ISRC) is enabled on the chosen SFx pin. To confirm that the SFx pin has then reached a suitable voltage level, a dedicated ADC measurement on the SFx pin can be requested. Once this test is performed, a leakage test on SFx and SRx pins can be issued to double check possible leakages.

Leakage to battery/ground diagnostics

Prior to the real test, the Voltage Regulator Current Monitor block (VRCM) has to be tested and validated. The validation of VRCM goes into verifying both the short to battery and short to ground flags.

The I_{source} current generator (ISRC) is first connected to SFx pin to raise its voltage to SYNCBOOST. Then, the Voltage Regulator Current Monitor block (VRCM) is enabled and

connected to the selected SFx pin. The I_{sink} current limited switch (ISNK) is turned off, as well as the pull-down current generator. If the VRCM block works properly, the short to battery flag would be asserted.

Then, the I_{sink} current limited switch (ISNK) is connected to SRx pin, the Voltage Regulator Current Monitor block (VRCM) is enabled and connected to the selected SRx pin. The I_{source} current generator (ISRC) is turned off, as well as the pull-down current generator. If the VRCM block works properly, the short to ground flag would be asserted.

Figure 35. SRx pull-down enable logic

Once the VRCM block is validated, the real leakage tests can be performed. ISRC and ISNK currents have to be kept switched off. The VRCM shall be connected to the desired pin (either SFx or SRx pins); by doing this, also the pull-down current on the selected SRx pin is automatically deactivated). During the test, if no leakage is present the voltage on the selected or sourced by the VRCM. If there is leakage to ground or battery, the VRCM will sink or source current trying to maintain VREF. Two current comparators, ISTB and ISTG, will detect the abnormal current flow and the relative flags will be given in the LPDIAGSTAT. These flags are not latched and report the real time status of the relevant comparators in case of low-level leakage diagnostic test. Voltage conversion is not required to have these flags updated. In LPDIAGSTAT register are also reported the channel and the pin (SFx or SRx) under test, respectively with LEAK_CHSEL and SQP bit fields.

The pull-down currents on the other SRx pins are still active. Therefore, the leakage test that would show a leakage to ground may be depending on a real leakage on the pin under test or on a short between loops.

Short between loops diagnostics

In case the previous test has reported a leakage to ground fault, the short between loops diagnostics shall be run. The same procedure is followed as described for normal leakage tests except the fact that in this case all the pull-down current generators have to be deactivated (not only the one for the pin under test), by means of the PD_CURR bit in the Diagnostic Request Register (LPDIAGREQ). If a leakage or ground fault is not present, then the channel under test has a short to another squib loop.

| Fault condition on squib channel | Channel leakage diagnostics with PD_CURR on (for other channels than the one under test | Channel leakage diagnostics with PD_CURR off (for all channels) |
|----------------------------------|---|---|
| No shorts | No fault | No fault |
| Short to battery | STB fault | STB fault |
| Short to ground | STG fault | STG fault |
| Short between loops | STG fault | No fault |

The condition of two open channels, i.e. without squib resistance connecting SFx to SRx, that have a short between loops on SFx cannot be detected. If only one of the two shorted SFx pins is open, the fault will be indicated on the open channel.

Squib resistance measurement

During a resistance measurement, a two-step process is performed. At the first step, both ISRC current generator and ISNK current limited switch are enabled and connected to the selected SFx and SRx channel, through ISRC, ISRC_CURR_SEL, ISNK and RES_MEAS_CHSEL bit fields in the Loop Diagnostic Request Register (LPDIAGREQ). The ISRC current can be configured to either 40 mA or 8 mA nominal value through the ISRC_CURR_SEL bit in the LPDIAGREQ register providing the user with two different measurement range options. A differential voltage is created between the SFx and SRx pin based on the ISRC current and squib resistance between the pins. The SPI interface will provide the first resistance measurement voltage (Vdiff1) based on the amplifying factor of the differential amplifier and a 10 bit internal ADC conversion. The second measurement step (bypass measurement) is performed redirecting ISRC to the selected SRx pin, while keeping ISNK on; this way, the differential amplifier and following ADC will output the offset measurement through SPI (Vdiff2). Microcontroller is then allowed to calculate the mathematical difference between first and second measurements to obtain the real squib resistance value.

$$V_{diff1} = G_{RSQ} \times \left[I_{SRC_*} \times \left(\frac{R_{LKG_SF} \times R_{SQ}}{R_{LKG_SF} + R_{SQ}} \right) + \frac{R_{SQ}}{R_{LKG_SF} + R_{SQ}} (V_{LKG_SF} - V_{SRx_RM}) \right] +$$

+
$$G_{RSQ} \times V_{off_RSQ}$$

$$V_{diff2} = \frac{G_{RSQ} \times R_{SQ}}{R_{LKG SF} + R_{SQ}} \times (V_{LKG_{SF}} - V_{SRx_{RM}}) + G_{RSQ} \times V_{off_{RSQ}}$$

$$R_{SQ} = \frac{V_{diff1} - V_{diff2}}{G_{RSQ} \times I_{SRC_{*}}} \text{ (assuming } R_{LKG_{SF}} >> R_{SQ})$$

The simplification in the calculation method reported above can result in some amount of error that is already incorporated in the overall tolerance of the squib resistance measurement reported in the electrical parameters table.

Values of each measurement step can be required addressing the proper ADCREQx code in Section 7.3.33: ADC request and data registers (DIAGCTRL_x).

This calculation is tolerant to leakages and, thanks to a dedicated EMI low-pass filter, also to high frequency noises on squib lines. Moreover, L9680 features a slew rate control on the ISRC current generator to mitigate emissions.

High squib resistance diagnostics

With this test, the device is able to understand if the squib resistance value is below 200 Ω , between 500 Ω and 2000 Ω or beyond 5000 Ω . During a high squib resistance diagnostics, VRCM and ISNK are enabled and connected respectively to SFx and SRx on the selected channel. VREF voltage level will be output on SFx. Current flowing on SFx will be measured and compared to I_{SRlow} and I_{SRhigh} thresholds to identify if the resistance is above or below RSRlow or RSRhigh levels. The results are reported in the LPDIAGSTAT register. The relative flags (HSR_HI and HSR_LO) are not latched and reflect the current status of the comparators.

High and low side FET diagnostics

This couple of tests can only be run during the diagnostic mode of the power-up sequence *Figure 11*. Tests are performed individually for HS driver or LS driver, with two dedicated commands. Prior to either the HS or LS FET diagnostics being run, the VRCM has to be first enabled. Within the command to enable the VRCM, also the channel onto which the FET test will be run has to be selected with the LEAK_CHSEL bit field. Running the leakage diagnostics with the appropriate delay time prior to either the HS or LS FET diagnostic will precondition the squib pin to the appropriate voltage level. When the FET diagnostic command is issued with the Diagnostic Register SPI command (SYSDIAGREQ), the VRCM flags will be cleared, the VRCM deglitch filter time is switched from the leakage diagnostic deglitch filter time (TFLT_LKG) to the FET test deglitch filter time (TFLT_LKGB_FT) for both HS and LS and the output of the VRCM deglitch filter is now allowed to disable the appropriate HS or LS squib driver during FET test.

The device monitors the current through the VRCM. If the FET is working properly, this current will exceed $I_{HS_FET_TH}$ or $I_{LS_FET_TH}$ current threshold, respectively for HS or LS FET test for the deglitch filter time of TFLT_LKGB_FT, and the driver under test is turned off immediately and automatically.

If there is a substantial leakage fault to Vbat or GND present during the FET test, leading this leakage current to exceed the IHS_FET_TH or ILS_FET_TH current threshold, for the deglitch filter time of TFLT_LKGB_FT, then the driver under test is turned off immediately and automatically, and the corresponding VRCM flag, STG or STB, is set.

If the current does not exceed the current threshold, the test will be terminated and the driver is anyway turned off within $T_{\mbox{FETTIMEOUT}}$

| VRCM Flags | | Result | |
|------------|-----|---|--|
| STG | STB | Result | |
| 0 | 0 | FET test fail | |
| 0 | 1 | FET test pass OR Leakage to Vbat | |
| 1 | 0 | FET test disabled due to Leakage to Gd | |
| 1 | 1 | State not possible | |

Table 12. LS FET TEST

| VRCM Flags | | Result |
|------------|-----|--|
| STG | STB | Result |
| 0 | 0 | FET test fail |
| 0 | 1 | FET test disabled due to Leakage to Vbat |
| 1 | 0 | FET test pass OR Leakage to GND |
| 1 | 1 | State not possible |

During T_{FETTIMEOUT} period, the bit stating that the FET is enabled will be set (FETON=1) and will be cleared as soon as the FET is switched back off.

For all conditions the current on SFx/SRx pins will not exceed the VRCM current limitation value ($I_{LIM_VRCM_SINK}$ or $I_{LIM_VRCM_SRC}$). There may be higher currents on the squib lines due to the presence of filter capacitors. During these FET tests, energy available to the squib is limited to less than E_{FET_TEST} . For high side FET diagnostics, if no faults were indicated in the preceding leakage diagnostics then a normal result would be [STB=1, STG=0]. If the returned result for the high side FET test is not as the previous then either the FET is not functional, a short to ground occurred during the test, or there is a missing SSxy connection for that channel.

For low side FET diagnostics if no faults were indicated in the preceding leakage diagnostics then a normal result would be [STB=0, STG=1]. If the returned result for the low side FET test is not as the previous then either the FET is not functional or a short to battery occurred during the test. In case of ground loss the low-side FET diagnostic would not indicate a FET fault.

The VRCM flags will be given in the LPDIAGSTAT register. The status of the VRCM flags after FET test is latched and can be cleared upon either LPDIAGREQ or SYSDIAGREQ SPI commands.

Finally, after FET test is completed, the VRCM deglitch filter time is switched from the FET test deglitch filter time (TFLT_LKGB_FT) to the leakage diagnostic test deglitch filter time

(TFLT_LKG) for both HS and LS and the output of the VRCM deglitch filter is now not allowed to disable the appropriate HS or LS squib driver anymore.

High side driver diagnostics

This test is intended to verify the proper functionality of the HS FET driver, but also the external squib connection and other internal circuitries.

First, the ISNK current has to be activated via the LPDIAGREQ register; the channel onto which the ISNK current is activated has to be selected with the RES_MEAS_CHSEL bit field. Then, the HS FET related to the loop channel as indicated in the RES_MEAS_CHSEL bit field is activated with the dedicated DSTEST code for the HS squib driver test in the Diagnostic Register SPI command (SYSDIAGREQ). In such condition, the HS driver will control the FET current to a level I_{LIM_HS_FET} much lower than the usual deployment current. The HS_DRV_OK flag will be set accordingly to the test result in the LPDIAGSTAT register, as soon as the deployment current monitoring comparator will detect that the current through the HS FET exceeds the diagnostic current threshold, 90%*I_{LIM_HS_FET}.

Loss of ground return diagnostics

This diagnostics is available during a squib measurement or a high side driver diagnostics. This test is based on the voltage drop across the ground return, if the voltage drop exceeds SG_{xy_OPEN} , ground connection is considered as lost. Should the ground connection on the squib driver circuit be missing, the bit related to the channel under test by the two above diagnostics will be activated in the LP_GNDLOSS register. The flag is latched after a proper filter time T_{FLT SGOPEN} and cleared upon read.

High side safing FET diagnostics

This test has to be issued during the Diag state of the power-up sequence (*Figure 11*). Safing FET has to be switched on with the proper code in DSTEST bit field of the SYSDIAGREQ. Therefore, when the command is received, the device will activate VSF regulator to supply the external safing FET controller. The user can measure the voltage levels of both the VSF regulator and the SSxy nodes. If the safing FET is properly switched on, the voltage on SSxy will be regulated.

The measurement request is done via Diagnostic Control command (DIAGCTRLx), while results will be reported through ADCRESx bit fields.

Deployment Timer diagnostic

This test allows verifying the correct functionality and duration of the timers used to control the deployment times. This test can be executed only when the IC is in the Diag state by setting the appropriate code in the DSTEST field of the SYSDIAGREQ register. When the test is launched, the IC sequentially triggers the activation of the deployment timers of the various channels (each of them separated by 8ms idle time) and outputs the relevant waveform to the ARM1 output discrete pin. See the sequence detail in *Figure 36*. The μ C can therefore test the deployment times by measuring the duration of the high pulses sent by the IC on the ARM1 pin. The deployment time configuration used during this test is the latest one programmed in the DCRx registers. In case the test is run on a channel with no DCRx deployment time previously configured, a default 8 μ s high pulse is output on ARM for the relevant channel.

Squib diagnostics with common SRx connected loops

In case of two SRx pins are intentionally connected together, the PD_CURR_CSR bit of the Deployment Configuration register (DCR_x, where x = 0, 2, 4, 6, 8, A) must be used to indicate which loop pairs have the common SRx connection. The purpose of this additional bit is to control the pull-down current on each channel to be consistent with or without the Common SRx connected loops. When the DCR_x(PD_CURR_CSR) bit is set for one loop pair and the Deployment diagnostic is run on that loop pair, the pull-down current is disabled on both channels of the loop pair selected.

For the squib channel pair with common SRx connection, to understand if the two SFx pins are shorted together, the squib resistance measurement must be required with the following setting: LPDIAGREQ[12:11]=11. In this way the ISRC current generator is enabled on the channel selected by RES_MEAS_CHSEL[3:0] bits while the Differential Operational Amplifier is connected on the other channel of the squib channel pair. If the short between the two SFx pin is not present then the Squib resistance measurement results will be close to 0, otherwise it will be half the real squib resistance.

Loop diagnostics control and results registers

Diagnostic tests and channels for each test are controlled through the Loop Diagnostic Request Register (LPDIAGREQ), diagnostic results are stored in the Loop Diagnostic Status Register (LPDIAGSTAT).

8.5.2 High level diagnostic approach

In this approach, the test steps described in the sections below are coded into a dedicated state machine that helps reducing the user intervention to a minimum.

The high-level diagnostic commands are contained in the LPDIAGREQ, LOOP_DIAG_SEL, and LOOP_DIAG_CHSEL registers. The high-level diagnostic response is available in the LPDIAGSTAT register.

The concept is depicted in the following figures.

Figure 38. High level loop diagnostic flow2

176/280

9 Remote sensor interface

The L9680 contains 4 remote sensor interfaces, capable of supporting PSI-5 protocol (synchronous mode, increased voltage, extended range) and active wheel speed sensors. A simplified block diagram of the interface is shown below. The interface supply is given on the SATBUCK pin (refer to *Figure 3: Power supply block diagram*). The circuitry consists of a power interface that mirrors current flowing in the external sensor and transmits this current information to the decoder, which produces a digital value for each remote sensor channel. The voltage at the RSUx pins can be limited by the power interface in case of SATBUCK supply overvoltage to protect the external sensors. Decoded data are then output through the Remote Sensor Data Registers (RSDRx). Received signals can be processed to the corresponding discrete logic output pin WS0-WS3. The power interface also contains error detection circuitry. When a fault is detected, the error code is stored in a global SPI data buffer in the Remote Sensor Data Registers (RSDRx).

Remote sensor configuration can be addressed via the Remote Sensor Configuration Registers (RSCRx). Some of the bit fields in the RSCRx registers are available depending on the chosen configuration, remote sensor rather than wheel speed sensors. In particular, TSxDIS bit allows overriding the time slot control for PSI5 I/F and BLKTxSEL allows selection between 5ms and 10ms for the blanking time applied to the current limitation fault detection each time a channel is activated.

The Remote Sensor Control Register (RSCTRL) allow for interface channels to be switched on and Off and for Sync Pulse control via SPI.

The remote sensor interface reports both data information and fault information in the Remote Sensor Data Register (RSDRx). The device accommodates for a total of 12 data registers. Independent data registers are defined for each remote sensor interface and are formatted differently based on whether the interfaces are programmed for PSI-5 remote sensor functions or active wheel speeds.

In the VDA sensor communication, data bit D0 in the RSDRx register might be used by the sensor as a fault bit. Therefore, this bit is latched as D0_L in order to detect whether a fault has occurred: the eight data bits are updated every speed pulse so intermittent fault conditions could be lost. This bit is cleared-upon-read.

If the device detects an error on the sensor interface, the MSB in RSDRx (FLTBIT) will be set to '1' and the following bits will be used to report the detected errors. Otherwise, the register will contain only data information. Detailed information on data and fault reporting are explained in the following sections.

When a fault condition is detected, the RSFLT bit of the global status word (GSW) is set to 1. Faults other than Short to Ground and Over-temperature will only clear after read, not by the disabling of channel.

Data are cleared upon reading the RSDRx register.

9.1 PSI5 mode

All channels are compliant to the PSI-5 v1.3 specification as described below:

- Two-wire current interface
- Manchester coded digital data transmission
- High data transmission speeds of 125 kbps and 189 kbps
- Variable data word length (8 & 10 bit only)
- 1-bit parity
- Synchronous operating mode with 3 time slots

An example of the data format for one possible PSI-5 protocol configuration is shown below. Data size and the error checking may vary, but the presence of 2 sync start bits (referenced below as sync bits) and 2 T_{Gap} time is consistent regardless.

Figure 40. PSI-5 remote sensor protocol (10-bit, 1-bit parity

9.1.1 Functional description

The Remote Sensor Interface block provides a hardware connection between the microcontroller and up to twelve remote sensors (maximum three per channel). Each channel is independent on the others, and is not influenced by possible fault conditions occurring on other channels, such as short circuits to ground or to vehicle battery. Each channel is supplied by a current limited DC voltage derived from SATBUCK, and monitors the current sunk from its supply in order to extract encoded data. The remote sensor modulates the current draw to transmit Manchester-encoded data back to the receiver. The current level detection threshold for all channels is internally computed by the IC in order to adapt the signal level to the sensors quiescent current.

All channels can be enabled or disabled independently via SPI commands. The operational status of all channels can also be read via SPI command. All channels support individual selective sync-pulse control to allow communication back to the remote sensor via sync-pulse voltage modulation as described in the PSI5 v1.3 specification.

The message bits are encoded using a Manchester format, in which logic values are determined by a current transition in the middle of the bit time. When configured for PIS5 sensors each interface supports Manchester 2 encoding as shown in *Figure 41*. When configured for VDA sensors the protocol supported is Manchester 1.

The sensor input filter time, deglitch filter, (delay until a threshold crossing is detected) can be configured in 15 steps. Filters can be selected individually for each channel, through the Remote Sensor Configuration Register, WSFILT bits

The received message data are stored in input data registers that are read out by the microcontroller via the SPI interface. For PSI5, three data registers per channel are used to store remote sensor messages received during timeslots 1, 2, and 3 respectively. Each register is updated after a certain delay (TWRITE_EN_DELAY) from the end of relative sensor message. All the bits inside the registers itself are simultaneously updated upon reception of the remote sensor message to prevent partial frame data from being sampled via the SPI interface. After the data for a given channel is read via the SPI interface, subsequent requests for data from this channel will result in an error response.

To allow for sampling synchronization of remote sensor data with the software in the microcontroller, the Remote sensor Interface block includes sync-pulse circuitry to signal initiation of sampling in the remote sensor. The sync-pulse is output to the remote sensors in the form of an increased voltage level on the RSUx pins when sampling is to be conducted. The higher voltage level required for the sync-pulse is sourced from the SYNCBOOST boost regulator. Pulse shaping is used to limit the slew rate of the pulses to reduce EMI. Feedback protection is provided to prevent fault conditions on one channel from affecting the others during sync-pulse generation. The microcontroller schedules the activation of the sync pulses to the four channels by providing a periodic signal to the SATSYNC pin. When a rising edge is detected on SATSYNC pin, the Remote sensor Interface block outputs sync pulses on channels RSU0-RSU3 in sequence to reduce the average current inrush to the remote sensors as shown in *Figure 42*. The voltage source in the Remote Sensor Interface block can source and sink current and is used to discharge the bus capacitance at the end of the sync pulse. The pull down device used to sink current is current limited.

Figure 42. Remote sensor synchronization pulses

L9680 supports three time slots in a sync period with associated RSDRx registers. The messages received within one sync period are routed to the corresponding RSDRx register associated to each time slot. A time slot control is performed to check if the incoming messages fall within the valid time slots reported in Table 62 and sketched in Figure 43 If the end of the received message occurs outside a valid time slot, a SLOT ERROR fault will be detected and stored in the related RSDRx register. Slot error assignment is described in Figure 43. For instance, if the end of second message falls before expected valid time window the error slot 1 is asserted and then also the data received with the first message is lost. If two messages end within the same slot, the second message will be assigned to that slot, regardless its validity. The time slot control can be disabled by setting the TSxDIS bit in the RSCRx register.

Figure 43. PSI5 slot timing control

The remote sensor interface is also able to detect faults occurring on the sensor interface. The Remote Sensor Data Register (RSDRx) will report multiple fault flags.

When the number of bits decoded is incorrect (either too many or too few), a bit error is indicated. When any bit error is detected (bit time, too many bits, too few bits), the decoder will revert to the minimum bit time of the selected range and the message is discarded.

Error bit INVALID is an OR-ed combination of the following errors:

- Start bit error outside of selected operating range
- Data length error or stop bit error
- Parity Error of received Remote sensor Message
- Bit time error (a data bit edge is not received inside the expected time window)

All fault bit related to channel error are loaded in the 3 time slot register and the fault has the priority, so the fault overwrite valid data.

9.1.2 Sensor data integrity: LCID and CRC

Each RSDRx data register contains a Logical Channel ID which is a 4/2-bit field for remote sensors used to link the received data to the corresponding logical channel number. Each RSDRx register contains also a CRC bit field computed on the data packet for data integrity check. To satisfy functional safety requirements LCID, DATA and CRC bit fields propagate through the same data path as a single item to the SPI output.

The polynomial calculation implemented for PSI5 data is described as in PSI5 specification $g(x)=1+x+x^3$ with initialization value equal to '111'.

Below are the equations to calculate the CRC in combinatorial way.

CRC[2] = CRCext[0]+D[0]+D[1]+D[3]+D[6]+D[7]+D[8]+D[10]+D[13]+D[14]+D[15]

CRC[1] = CRCext[2]+D[0]+D[1]+D[2]+D[4]+D[7]+D[8]+D[9]+D[11]+D[14]+D[15]+D[16]

CRC[0] = CRCext[1] + CRCext[0] + D[0] + D[2] + D[5] + D[6] + D[7] + D[9] + D[12] + D[13] + D[14] + D[16]

Where D[16:0]= RSDR[16:0] and CRCext[n] are the starting seed values (all '1').

9.1.3 Detailed description

Manchester decoding

The Manchester decoder will support remote sensor communication as per PSI specification rev 1.3 for the modes configurable via the STS bits in the RSCRx registers. The Manchester Decoder checks the duty-cycle and period of the start bits to determine their validity, depending on the configuration of the PERIOD_MEAS_DISABLE bit in the RSCRx registers. The expected time windows for the mid bit transitions of each subsequent bit within the received frame are determined by means of the internal oscillator time base. Glitches shorter than 25% of the minimum bit time duration are rejected.

DS11615 Rev 2

A Manchester Decoder Error occurs if one or more of the following are true:

- Two valid start bits are detected, and at least one of the expected 13 mid-bit transitions are not detected
- Two valid start bits are detected, and more than 13 mid-bit transitions are detected
- When the number of bits decoded is incorrect (either too many or too few), a bit error is indicated. When any bit error is detected (bit time, too many bits, too few bits), the decoder will revert to the minimum bit time of the selected range and the message is discarded.

The Manchester decoder re-initializes at the start of each timeslot, such that remote sensor frames violating timeslot boundaries will result in the setting of a Manchester Error. All errors are readable through the Sensor Fault Status Register and the RSFLT bit in the Global Status Word Register.

When a valid message is correctly decoded, the 10/8 data bits are stored into the appropriate RSDRx register together with the related LCID. The RSDRx register contains the 10/8 bits data as they are received from the sensor (no data range check/mask is done at this stage). The 8-bit data word is right-justified inside the 10-bit data field in the RSDRx registers.

Current sensor w/ auto-adjust trip current

The current sensor is responsible for translating the current drawn by the sensor into a digital state. Each remote sensor channel has a dedicated current sensor.

The current flowing through the RSU power stage is internally downscaled by a factor 100, sent to a 10 bits A/D converter and digitally processed to extract both the sensor quiescent and delta currents.

The delta current threshold for signal detection can either be fixed or auto-adjusted to the actual calculated sensor delta current, depending on the FIX_THRESH bit setting in the RSCRx registers.

The current trip point is dynamically determined by adding the delta current threshold (fixed/auto-adjusted) to the quiescent current (auto-adjusted). The RSU current is compared against the current trip point to determine the current demodulator digital output. A logic '1' represents the sensor current above the current trip point. The current demodulator output is fed into the Manchester decoder and optionally to the WSx discrete output pins, depending on the configuration of the RSPTEN bit in the RSCRx registers.

Thanks to the quiescent and delta current tracking features the receiver is capable to automatically adapt to different nominal sensor currents and/or to be tolerant to sensor current drifts over lifetime.

Both the sensor quiescent and delta current tracking algorithms can be configured by setting appropriately the REDUCED_RANGE, BLOCK_CURR_IN_MSG and AVG/SSDIS bits in the RSCRx registers.

9.2 Active wheel speed sensor

The remote sensor interface circuit conditions and decodes active wheel speed sensor signals with various pulse widths and output currents. The following sensor types are supported and selected through the Remote Sensor Configuration Register (RSCR)

- Standard active 2-level wheel speed sensors (7/14 mA)
- Three level (7/14/28 mA) VDA compliant sensor with direction and air gap information ('Requirement Specification for Standardized Interface for Wheel Speed Sensor with Additional Information', Version 2.0)
- PWM encoded 2-level sensors with 2 edges per tooth (see data sheet Infineon® IC TLE4942/BOSCH DF11)
- PWM encoded 2-level sensors with 1 edge per tooth (see data sheet Allegro® ATS651LSH/BOSCH DF11)

Received wheel speed frames from all the above sensors are decoded into signals suitable for the microcontroller through the four WSx output pins (WS0-WS3). Specific information is shown in *Figure 45*.

For all sensors, other than the standard active 2- level sensor, additional sensor data (diagnostics, etc...) are decoded and available within the Remote Sensor Data Registers (RSDR0, RSDR1, RSDR3, RSDR4). If standard active 2- level sensor is selected the content of the Remote Sensor Data Registers will be NO DATA fault.

Only for 2-level sensors (STD or PWM encoded) the user may choose to have all sensor data processed through the microcontroller by selecting pass through mode, WSPTEN, within the Remote Sensor Configuration Register (RSCR). In pass through mode, the remote sensor interface simply transforms the incoming sensor current pulses to digital voltage pulses on the WSx pins, no decoding is performed.

The sensor input filter time, deglitch filter (delay until a threshold crossing is detected) can be configured in 15 steps. Filters can be selected individually for each channel, through the Remote Sensor Configuration Register, WSFILT bits.

For PWM encoded sensors with 2 edges per tooth not in pass through mode, the standstill signal can be processed directly to the WSx output pins. This is done in the Remote Sensor Configuration Register, SSEN bit.

Since the decoder has to measure the pulses in order to determine, whether they are standstill pulses or not, the first standstill pulse will always be seen on the WSx output pins and the first not stand-still pulse after a stand-still period will be suppressed.

For 3-levels VDA sensors the device performs parity check on the received data frame. In case a parity error is detected, the INVALID fault bit of the RSDRx register will be set.

Data from the sensor are not latched: last incoming frame overwrites the previous one once validated. Faults coming from diagnostic (i.e. over current, short to ground or battery) are latched until the microcontroller reads them.

Sensor signal decoding is done according to two possible algorithms:

• Auto-adjusting current trip points.

With this option, the IC is able to find sensor DC current value (named IB0) in the range from 2.5 mA to 21 mA (default is 7 mA).

The IC is also able to detect the current value of the data pulse and compute the first threshold (named Ith1): Ith1 = IB0 + Δ Ith1/2 where Δ Ith1 is in the range from 5 mA to 9.3 mA (default is 7 mA).

Besides, in case of VDA selected, the ASIC is also able to recognize the current value of the speed pulse by computing a second threshold (named Ith2): Ith2 = IB0 + Δ Ith1 + Δ Ith2/2 where Δ Ith2 in the range from 10 mA to 18.6 mA (default is 14 mA)

• Fixed current trip points where the thresholds are set via SPI. The default value for first threshold is 9.8 mA and for second threshold is 19.6 mA

Figure 45. Wheel speed sensor protocols

9.2.1 Wheel speed data register formats

When programmed as a wheel speed sensor interface, only four data registers are used (Remote Sensor Data Register RSDR0-RSDR3).

Independent data registers are defined for each wheel speed channel and their contents are determined by sensor type. Three level VDA sensors have eight data bits and. At fast wheel speed not all bits may be transmitted by the sensor: the IC is able both to process normal or either truncated frames by providing together with data, a 4 bit counter to inform the microcontroller about the number of received valid bits.

For PWM encoded sensors, each pulse length is written to the sensor data register with a typical resolution of 5 μ s per bit. In case of pulse width duration equal or higher than $T_{STANDSTILL_TH_L}$ and less or equal than $T_{STANDSTILL_TH_H2}$, the standstill condition will be recognized and bit 15 in the corresponding register will be set.

The register is updated when a PWM falling edge is detected; in case of stuck-at 1 of the PWM signal the register is updated when the counter reaches the overflow value (0x1FF): in this case the standstill bit not set and the counter in overflow will signal a fault to the microcontroller.

9.2.2 Test mode

In order test the input structures of the connected microcontroller, the L9680 features a wheel speed test mode that allows test patterns to be applied on the four wheel speed outputs WS0-WS3. The test mode can be entered via SPI and the test patterns can also be controlled via SPI commands. Test patterns can be composed only of static high or low signals, which can be selected via SPI. For failsafe reasons only one channel at a time can be switched into test mode.

9.3 Remote sensor interface fault protection

9.3.1 Short to ground, current limit

Each output is short circuit protected by an independent current limit. Should the output current level reach or exceed the ILIMTH for a time period greater than TILIMTH or the remote sensor interface the output stage is disabled. An internal up-down counter will count in 25 µs increment up to TILIMTH. The filter time is chosen in order to avoid false current limit detection for in-rush current that may happen at interface switch-on. When the output is turned off due to current limit, the appropriate fault code STG is set in the Remote Sensor Data Register (RSDR). The fault timer latch is cleared when the sensor channel is first disabled and then re-enabled through the Remote Sensor Control Register (RSCTRL). This fault condition does not interfere neither with the normal operation of the IC, nor with the operation of the other channels. When a sensor fault is detected, the RSFLT bit of the GSW is set indicating a fault occurred and can be decoded by addressing the RSDR register.

In order to fulfill the blanking time requirement at channel activation as per PSI-5 specification, a dedicated masking time is applied to the current limitation fault detection each time a channel is activated.

9.3.2 Short to battery

All outputs are independently protected against a short to battery condition. Short to battery protection disconnects the channel from its supply rail to guarantee that no adverse condition occurs within the IC. The short-to-battery detection circuit has input offset voltage (10mV, minimum) to prevent disconnecting of the output under an open circuit condition. A short to battery is detected when the output RSUx pin voltage increases above SATBUCK or SYNCBOOST (depending on operation) supply pin voltage for a T_{STBTH} time. An internal up-counter will count in 1.5 μ s increment up to T_{STBTH}. The counter will be cleared if the short condition. Other channels are not affected in case of short of one output pin. As in the case previously described, the STB fault code can be read from RSDR bits and any fault will set the RSFLT bit of the global status word register (GSW). The STB bit is cleared upon read or upon channel disabled via SPI RSCTRL register.

9.3.3 Cross link

The device provides also the capability of a cross link check between outputs, in order to reveal conditions where two output channels are in short. This functionality is allowed by enabling one output channel, while asking for voltage measurement on any of the other ones.

9.3.4 Leakage to battery, sensor open

The sensor interface offers also open sensor detection. The auto-adjusting counter for remote sensor current sensing will drop to 0 in case the current flowing through RSUx pin is lower than 2.5 mA typ. The OPENDET fault flag is asserted when the fault condition lasts for longer than TRSUOP_FILT deglitch filter time. This fault flag can be read from RSDR bits and any fault will set the RSFLT bit of the global status word register (GSW). The channel in this condition is not shutdown. This fault bit is cleared upon read or upon channel disabled via SPI RSCTRL register.

9.3.5 Leakage to ground

The sensor interface offers as well the detection of a leakage to ground condition, that will possibly raise the sensor current higher than 42 mA/12 mA typ in PSI5/WSS modes respectively. The CURRENT_HI fault flag is asserted when the fault condition lasts for longer than T_{RSUCH_FILT} deglitch filter time. This fault flag can be read from RSDR bits and any fault will set the RSFLT bit of the global status word register (GSW). The channel in this condition is not shutdown. This fault bit is cleared upon read or upon channel disabled via SPI RSCTRL register.

9.3.6 Thermal shutdown

Each output is protected by an independent over-temperature detection circuit should the remote sensor interface thermal protection be triggered the output stage is disabled and a corresponding thermal fault is latched and reported through the RSTEMP flag in the Remote Sensor Data Register (RSDRx). The thermal fault flag is cleared when the sensor channel is first disabled and then re-enabled through the Remote Sensor Configuration Register (RSCRx).

10 Watchdog timers

This device offers a 2-level watchdog control approach. The first control level is given by means of a temporal watchdog (WD1). The WD1 window times are SPI programmable and a couple of specific codes have to be written within this window in order to serve the WD1 control. The second control level is featured by an algorithmic seed/key watchdog (WD2). Unlike the temporal watchdog, the algorithmic watchdog service must be maintained before a timeout occurs, i.e. there is no restriction on refreshing the watchdog too early. Both WD1 and WD2 watchdog functionalities can be tested trough the WD_TEST SPI command.

10.1 Temporal watchdog (WD1)

The temporal watchdog ensures the system software is operating correctly by requiring periodic service from the microcontroller at a programmable rate. This service (watchdog refresh) must occur within a time window, and if serviced too early or too late will enter an error state reported via the FLTSR register (WD1_WDR bit).

The overall WD1 functionality is described in the state diagram reported in Figure 46.

Figure 46. WD1 Temporal watchdog state diagram

Following the description of the WD1 states and signals (most of them reported in related SPI registers)

 $\langle \nabla \rangle$

| State/Signal | Description | | |
|--|---|--|--|
| WD1 INITIAL | Default state entered from startup. While in this state, no watchdog service is required, and the IC may stay in this state indefinitely. For system safety, all arming signals are disabled during this state to prevent deployment. | | |
| WD1 RUN | Normal run time state where WD1 service is required. | | |
| WD1 TEST | A special state used to test the watchdog function. Normally, this state will only be checked once per power cycle by the software, but there is no inherent restriction in the watchdog logic preventing periodic testing. This state allows testing of the watchdog without setting WD1_LOCKOUT=1, which can only be cleared via WSM reset. Deployment is inhibited when the WD state machine is in this state. | | |
| WD1 RESET | State entered when a WD1_ERROR occurs. This is a timed-duration state that is automatically exited after 1ms. | | |
| WD1 OVERRIDE | A special state used to disable watchdog functionality for development purposes. Other logic within the IC can use this state to emulate the WD1 RUN state without the need to service WD1. | | |
| WSM_RESET | Signal used to reset the WD1 state machine to the WD1 INITIAL state and all signals to their inactive values | | |
| WD1_refresh OK | Signal that is asserted only if the watchdog is refreshed ('A' - 'B' or 'B' - 'A' seq.) within the WD1 time window | | |
| WD1_ERROR | Signal that is asserted if the watchdog refresh fails to occur during the WD1 time window. | | |
| WD1_WDR | Watchdog Reset – latched signal that is activated whenever a watchdog error is qualified. For WD1, this occurs when WD1 service is required, but not received. This signal is SPI-readable. | | |
| WD1_TM | Test Mode – a signal that indicates that WD1 is being tested. This signal is SPI-readable. | | |
| WD1_LOCKOUT A latched signal activated if an unexpected WD1 error occurs. This sign permanently latched when set (until WSM_RESET). When set, all arming are disabled, preventing deployment. This signal is SPI-readable. | | | |
| SPI_WD1_TEST SPI command used to enter WD1 TEST state from WD1 RUN state, or to WD1 OVERRIDE state from INITIAL state if WDT/TM pin voltage is greate the threshold. This command has no effect in other states. | | | |

Table 13. Watchdog timer status description

10.1.1 Watchdog timer configuration

The watchdog timer can be configured on two different frequency modes:

- Fast watchdog with maximum range of 2ms and a resolution of 8 μs;
- Slow watchdog with maximum range of 16.3ms and a resolution of 64 μs.

The watchdog window times are SPI programmable. The configuration of watchdog timer frequency and window times can be done by setting the Watchdog Timer Configuration Register (WDTCR) with the appropriate values. However, this configuration is accepted only when the device is in the Init operating state, as shown in *Figure 11*. As soon as the device enters in Diag state, the watchdog control is enabled and the watchdog configuration is fixed and cannot be changed anymore.

10.1.2 Watchdog timer operation

While in the WD1 INITIAL state, watchdog service must begin or a SPI command with WD1 TO DIS=1 must be received within the first 500 ms. If the WD1 Timeout Disable bit is set, the device can stay in the WD1 INITIAL state indefinitely without watchdog service.

To refresh WD1, the logic must receive a Watchdog Timer Register (WD1T) SPI command containing the expected key value within the WD1 time window (WDTMIN+WDTDELTA). If it is received too early, too late the WD1 ERROR signal will be asserted. The WD1 ERROR will not be asserted in case a SPI command containing the Watchdog Timer Register (WD1T) with an incorrect key value is received at any time relative to the window. This allows the system software to repeatedly transmit the key value until it needs to change to the correct key value. Upon reception of the correct key within the window, the logic will reset the watchdog timer to create a new window.

The timer is cleared upon writing code 'A' and code 'B' (either in 'A' - 'B' or 'B' - 'A' sequences) to the WD1CTL [1:0] bits, in the WD1T register. The watchdog timer value can be read via the WD1T register.

Algorithmic watchdog (WD2) 10.2

The algorithmic watchdog (WD2) is intended to protect higher software layers, and as such requires servicing at a much slower rate and allows for software jitter as compared with WD1. Additionally, WD2 is not implemented as a window watchdog, but is a maximum-time watchdog, where refresh is accepted at any time before the timer expires.

The overall WD2 functionality is described in the following state diagram:

Following the description of the WD2 states and signals (most of them available through SPI registers)

| Table 14. WD2 states and signals | | | | |
|----------------------------------|--|--|--|--|
| State / Signal | Description | | | |
| WD2 INIT | Default state entered from startup or after a SSM reset (if not in WD2 STOP state). | | | |
| WD2 OVERRIDE | Special state used to disable WD2 watchdog functionality. | | | |
| WD2 INITSEED | State entered when the correct default key is received in INIT state. Here the timer starts to count waiting for the real first key. | | | |
| WD2 RUN | Normal run-time state where WD2 service is required. | | | |
| WD2 TEST | A special state used to test the watchdog function. Normally, this state will only be checked once per power cycle by the software, but there is no inherent restriction in the watchdog logic preventing periodic testing. This state allows testing of the watchdog without affecting WD2 error (no reset is generated, WD2_LOCKOUT stay low). Only WD2_WDR latch could be set to 1, in this way μ C is able to verify the functionality of the watchdog. | | | |
| WD2 QUAL | A state used to qualify a number of WD2_ERROR occurrences before action is taken. The intent is to use this state to permit a retry strategy to account for software jitter. | | | |
| WD2 LOCK | A state entered after the allowed retries have been exhausted. This is where action is taken due to WD2 service failure. | | | |
| WD2 STOPPING | This is a timed-duration state that is automatically exited after 1ms | | | |
| WD2 STOP | A state used to prevent continual recovery of WD2 errors using the WD2_KEY key mechanism to restart watchdog service. | | | |
| WD2 RESET | State entered when a WD2_ERROR occurs after having been qualified in the WD2_QUAL state (when all retries are exhausted), or when testing the WD2. This is a timed-duration state that is automatically exited after 1ms. | | | |
| WSM_RESET | Watchdog State Machine reset – used to force a transition to the WD2 INIT state and reset all signals to their inactive states | | | |
| WD2_RETRY | Counter that tracks the number of retry attempts. It is incremented each time the logic detects a WD2 error while qualifying the error. | | | |
| WD2_WDR | Watchdog Reset – latched signal that is activated whenever a watchdog error is qualified. For WD2, this occurs when WD2 service not received after all retry attempts have previously failed. This signal is SPI-readable. | | | |
| WD2_TM | Test Mode – a signal that indicates that WD2 is being tested. This signal is SPI-readable. | | | |
| WD2_LOCKOUT | A latched signal that is activated on startup, or whenever a WD2 error is fully qualified (all retry attempts have failed). Recovery is still possible after this is set going into WD2 RUN state. This signal drives the WD2_LOCKOUT output pin. This signal is SPI-readable. | | | |
| SPI_WD2_TEST | SPI command used to enter WD2_TEST state or to enter WD2 OVERRIDE state from INIT. | | | |
| TMR2 | Timer to count the maximum time limit to receive the correct key | | | |
| SPI_WD2_RECOVER | SPI command used to clear retry counter | | | |
| WD2_ERR_CNT | Counter that tracks the number of WD2 error occurred | | | |

Table 14. WD2 states and signals

To refresh WD2, the logic must receive a WD2_KEY command containing the expected key value before the WD2 timer expires. If it is received too late the refresh criteria have not been met. The WD2 error is asserted if the refresh does not occur before the end of the timeout. The WD2 error is not asserted if it receives continuously a WD2_KEY command with the correct key. This allows the system software to repeatedly transmit the correct key value at any rate faster than the required timeout.

Upon reception of the correct key, the logic will generate a new seed value, then calculate a new key using the new seed and reset the watchdog timer to create a new timeout.

When in WD2 INITSEED state, the three steps above are executed anyway. The seed is latched from a free-running counter that starts when WSM is released. The WD2_KEY command is used for transmission of the watchdog key, while WD2_SEED command is used to read the new seed and the previous key.

The SEED is generated by latching the value from a free-running counter. The free-running seed counter runs at a rate of f_{WD2_SEED} as specified in *Table 29*. The key value and seed value are 8-bits in length. The key shall be calculated as follows: (KEY = SEED \ddagger PrevKEY + \$01) where \ddagger denotes a bit-wise XOR operation

10.3 Watchdog reset assertion timer

Upon either a WD1 or a WD2 watchdog reset, the watchdog logic will momentarily assert the RESET pin for time duration $T_{WDT1_RST} / T_{WDT2_RST}$. When the RESET pin has been asserted through the watchdog reset assertion timer, stored faults are maintained and can be read by the microcontroller via SPI following the RESET period.

10.4 Watchdog timer disable input (WDT/TM)

This input pin has a passive and active pull-down and is used to disable the watchdog timer. The state of this pin can be read by SPI through the WDT/TM_S bit in the GSW register. When WDT/TM pin is asserted, the watchdog timer is disabled, the timer is reset to its starting value and no faults are generated.

The WDT/TM input pin must not be biased HIGH (WDT/TM > V_{WDTDIS_TH}) prior to POR in order to have a proper start-up.

11 DC sensor interface

L9680 implements a circuitry able to interface with a variety of positioning sensors. The sensors that can be connected to the device are Hall-effect, resistive or simple switches.

Range of measurements is:

- Resistive sensor: 65 Ω to 3 k Ω
- Hall-effect sensor: 1 mA to 2 0 mA.

Within the above ranges, accuracy of $\pm 15\%$ is granted. A reduced accuracy is given in the range 1 mA to 2 mA. Hall sensor and switch interface block diagram is shown below.

Figure 49. DC sensor interface block diagram

The global SPI contains several bits to control and configure the interface. The SWOEN bit is used to enable the output voltage on DCSx pins. The channel to be activated can be chosen by accordingly setting CHID bits. The interface activation is started and switched off upon user SPI command. Alternatively it could be configured via the SYS_CFG(EN_AUTO_SWITCH_OFF) bit to automatically switch off as soon as the measurement is complete, in case of current or resistance measurements; this would help preventing thermal conditions. The interface would not auto-switched off in case of voltage measurement, instead.

The device offers the capability to actively keep all the DCSx lines discharged by means of a weak pull down. The pull down is active by default on all channels and it is deactivated in either of the following cases:

- 1. when the voltage source is active on the relevant channel
- 2. when a voltage measurement is requested on the relevant channel
- 3. if SPI bit SWCTRL(DCS_PD_CURR) is set (global pull-down disable for all channels)

In case of Hall-effect sensors, a single current measurement is processed. The current load needed for regulating the pin is internally reflected to a reference resistance, whose voltage drop is then measured through the internal ADC converter.

When resistive or switch sensors are used, a more complex measurement is performed. In a first step the current information as above described is provided. Then, also the information on the voltage level achieved on the output pin is provided via ADC. By processing these two values, the micro-controller can understand the resistive value. The DCSx voltage is internally rescaled by a voltage divider into the ADC converter voltage range as shown in Figure 48. Additionally a positive voltage offset is internally applied to the scaled voltage in order to allow voltage measurement capability for DCSx down to -1V.

In order to get accurate resistive information even in case of an external ground voltage shift on the sensor of up to +/-1V, the voltage measurement step actually needs two DCSx voltage measurements. A first voltage measurement has to be done with selection of 6.25V on the output channel and a second one with the regulator switched off. The difference between the two measurements will cancel out the offsets (both external ground shift and internal offset).

The DCSx current and voltage can be retrieved from ADC readings according to the following formulas and related parameters specified in the Electrical Characteristics section.

$$I_{DCSx} = 100 \cdot \frac{I_{REF_DCS}}{2} \cdot DIAGCTRLn(ADCRESn) \quad @DIAGCTRL(ADCREQn = $04)$$
$$V_{DCSx} = RATIO_{VDCSx} \cdot \left(\frac{ADC_{REF_hi}}{2} \cdot DIAGCTRLn(ADCRESn) - V_{OFF_DCSx}\right) - V_{OFF_DCSx} \cdot (RATIO_{VDCSx} - 1) \quad @DIAGCTRLn(ADCREQn) = $03$$

The DCSx sensor resistance can be calculated according to the following formula:

$$\mathsf{R}_{\texttt{sensor}_{x}} = \frac{\Delta \mathsf{V}_{\texttt{DCSx}}}{\mathsf{I}_{\texttt{DCSx}}} = \frac{\mathsf{V}_{\texttt{DCSx}} \textcircled{(SWCTRL(SWOEN)=1-\mathsf{V}_{\texttt{DCSx}} \textcircled{(SWCTRL(SWOEN)=0)}}{\mathsf{I}_{\texttt{DCSx}}}$$

@SWCTRL(CHID) = x

The device provides also the capability of a cross link check between outputs, in order to reveal conditions where two output channels are in short. This functionality is allowed by enabling one output channel, while asking for voltage measurement on any of the other ones.

DS11615 Rev 2

L9680

Each output is protected against

- Overload conditions by current limit
- Ground offset between the ECU and the loads of up to ±1 V.
- Loss of ECU battery
- Loss of ground
- Unpowered shorts to battery
- Shorts to ground

11.1 Passenger inhibit interface

L9680 provides a feature to deactivate passenger restraint devices based on a preprogrammed mask. It generates a signal (PSINHINT) based on microcontroller-initiated measurements performed on DC Sensor channel 0. The PSINHINT signal is bitwise AND-ed with the LOOP_MATRIX_PSINH mask register, allowing selective deactivation of squib loops independent of microcontroller control. This signal is also inverted and output on the PSINHB pin of the IC to activate externally controlled squib loops.

An upper and lower threshold is preprogrammed via SPI by writing the desired 10-bits values into the PADTHRESH_HI and PADTHRESH_LO registers during the Diag state. These thresholds define the measurement window where the passenger restraints are active. Any measurement outside this window will result in the assertion of the PSINHINT signal (as described below), thereby deactivating the squib loops identified in the PSINH mask. The PSINH mask is also preprogrammed during the Diag state.

Another control (DCS_PAD_V bit in SYS_CFG register) is preprogrammed to select either a voltage measurement or a current measurement on DCS0 for this purpose.

The automated control of the PSINHINT signal occurs when the microcontroller runs diagnostic testing of the DCS0 interface. A 1 second timer is included to ensure the diagnostic test is run periodically. When the timer expires (down-counts to 0), the PSINHINT signal is asserted. When the measurement of the DCS0 voltage or DCS current (as selected by the DCS_PAD_V bit) is taken, and the value falls within the preprogrammed window, the timer will be reloaded. If the measurement is outside the window, the timer will not be reloaded, and it will continue to count down until it expires, resulting in activation of PSINHINT. For testing purposes, the PSINHINT can be controlled directly via SPI while in DIAG state using the Diag State Test Selection (DSTEST) register.

12 Safing logic

12.1 Safing logic overview

The integrated safing logic uses data from on-board and remote locations by decoding the various SPI communications between the interfaces and the main microcontroller. The safing logic has several programmable features enabling its ability to decode SPI transmissions and can process data from up to 16 sensors. The operating mode involves simple symmetrical data threshold comparisons, with the use of symmetrical or asymmetrical counters. A high level diagram is shown in the figure below. Please note that this top-level diagram is simplified, and references more detailed flowcharts to show a) message decoding, b) valid data limits, c) effects of the 'combine' function, d) comparison to thresholds and arming, and e) the setting of the 'compare complete bit. Four independent arming outputs, ARM1INT, ARM2INT, ARM3INT and ARM4INT, are also mapped internally to any of the integrated squib drivers.

Figure 51. Top level safing engine flow chart

DS11615 Rev 2

12.2 SPI sensor data decoding

Sensor data is regularly communicated with the main microcontroller through multiple SPI messages. The L9680 monitors SPI traffic on MISO_RS bus. Since not all communications between sensors and the microcontroller contain data, it is important for the decoder to properly sort the communications and extract only the targeted data. The solution involves defining specific masking functions, contained within independent safing records, programmed by the user. The following figures detail the SPI message decoding methodology and the ensuing comparisons of valid sensor data to the programmed thresholds.

Figure 52. Safing engine – 32-bit message decoding flow chart

Figure 53. Safing engine – 16-bit Message decoding flow chart

Figure 54. Safing engine - Validate data flow chart

201/280

Figure 55. Safing engine - Combine function flow chart

DS11615 Rev 2

204/280

DS11615 Rev 2

Each safing record has SPI accessible registers defined in the SPI command tables and summarized below:

- Request Mask and Request Target to understand what sensor the microcontroller is addressing
- Response Mask and Response Target to identify the sensor response
- Data Mask to extract relevant sensor data from the response.
 - Sensor data is extracted as a bit-wise AND result of the SAF_DATA_MASKx and monitored RS_MISO data. The configuration of the set bits of the DATAMASK must be contiguous for both 16-bit and 32-bit records. The 32-bit records are comprised of Part1 as MSW and Part2 as LSW.
 - The extracted data is then right justified into a 16/32 bit register for 16/32 bit safing records, respectively, prior to further processing steps which assume data is signed should be "using two's complement representation".
- Safing Threshold specific value that sets the comparator limit for successful arming
- Control:
 - IF, In Frame to indicate serial data response is 'in frame'. There are two types of potential serial data responses, 'in frame' and 'out of frame'.
 - CS to align safing record with a specific SPI CS. The device contains 5 SPI CS inputs for the safing function (CS_RS, SAF_CSx)
 - ARM there are four internal arming signals, each active record is assigned or mapped to any arming signal. Several safing records can be mapped to a single arming output. ARMx outputs can be enabled also simultaneously.
 - Dwell Once an arming condition is detected, the safing record remains armed for the specified dwell time.
 - Comb (Combined Data) specific solution for dual axis high-g sensors specifically oriented off-axis.
 - LimEn (Limit Enable) to enable PSI5 out-of-range control.
 - LimSel (Limit Select) to select PSI5 out-of-range thresholds between 8-bit and 10-bit protocol.
 - SPIFLDSEL (SPI Field Select) to determine which 16-bit field in long SPI messages (>31 bit) to use for response on MISO of SPI monitor. Don't care for messages less than 32 bits.

If input packet matches multiple safing records, the safing engine should process all of them and treat them independently.

Safing record can only be evaluated on the first matching input packet. Any further data packet matches are ignored (i.e. once CC is set, record can't be processed until CC is cleared)

The En (Record Enable) bit for any record is programmable as on or off at any time and will enable/disable the record itself upon the following SATSYNC.

All CC bits are available in one register (SAF_CC) for access in one single SPI read. After ARMing is achieved and CC is set, no further messages are considered until CC is cleared via read.

Safing Engine must not process sensor data in any state but Safing state (refer to *Figure 11*).

All safing records are cleared on SSM RESET.

Comb (Combined Data) bit allows combining X and Y for off-axis oriented sensors. In this case, it is typical for such orientations to add or subtract the sensor response to translate the sensor signal to an on-axis response. Only couples of 16-bit long records have this feature (i.e. 1&2, 3&4, 5&6, 7&8, 9&10, 11&12).

Records are added and subtracted and results compare against two thresholds. Safing engine will process data as follows:

- Use record(n) and record(n+1), where n = 1, 3, 5, 7, 9, 11.
- The matching inputs used for math combinations are processed only after both are captured.
- The sum of the two matching inputs will be compared to the threshold of record(n).
- The difference of the two records will be compared to the threshold of record(n+1).
- If the Comb feature was enabled on only one of the two records in a couple, math would be performed only on it as shown in *Figure 56*

Example of Combine Function operation:

| Record # | Combine Bit | Data | Resulting value | Record Threshold | ARMSELx Configuration | ARMINTx Result |
|----------|----------------|------|-----------------|---------------------|--------------------------|-------------------|
| | | | | | | |
| | | | | | | |
| | | | | | | |
| | | | | | | |
| | | | | | | |
| | | | | | | |
| | | | | | | |
| | | | | | | |
| | | | | | | |
| | | | | | | |

Table 15. Example of combine function operation

All items in the safing records, except En(Record Enable) bit, can be configured only in Diag state (refer to *Figure 11*). Additionally, the global bit to select internal or external safing engine is set in Init state.

12.3 In-frame and out-of-frame responses

Some sensors will communicate data within the current communication frame while others will send data on the next communication frame. Sometimes this is sensor specific and sometimes this is due to the amount of data to be transmitted. A simplified diagram shows the basic communication differences of in and out of frame responses.

In-frame example:

| | gure oo. m-na | | |
|------|---------------|------------|-------------|
| | | | |
| MOSI | Request n | Unused | |
| | | × | · |
| MISO | Status | Response n | |
| | | • | GAPGPS01143 |

Figure 58. In-frame example

At least one bit needed to allow for synchronization between clock domains (SPI clock and system clock).

Out-of-frame example:

| • | igure con out of | nume example | |
|------|------------------|--------------|-------------|
| MOSI | Request n | Request n+1 | |
| MISO | Request n-1 | Response n | GAPGPS01144 |

Figure 59 Out-of-frame example

Synchronization between clock domains relies upon inter-frame gap.

12.4 Safing state machine operation

State machine operation is disabled when the safing state machine reset signal is active as described in the power supply diagnostics and controls section of this document. The outputs of the state machine are ARMxREQ. As previously stated, there is a maximum of 16 safing records available to the state machine. Inputs to the safety state machine are programmed safing records and sensor data. The configuration of the state machine is common to all sensors.

12.4.1 Simple threshold comparison operation

In this mode, sensor data received through the sensor SPI interface and validated by the safing record is passed to the safing algorithm. The simple threshold comparison algorithm compares the received data to two thresholds, SAF_TH (positive threshold) and (-SAF_TH) (negative threshold). If the sensor data is greater than SAF_TH or is less than (-SAF_TH) then and event is flagged and the event counter is incremented based on the programmed value of ADD_VAL. If sensor data does not trigger the SAF_TH comparators, the counter is decremented by SUB_VAL. SUB_VAL is programmed by the user and can be same or different than ADD_VAL. This feature allows for an asymmetrical counter function making the system either more or less sensitive to sensor data. Since sensor data can indicate a positive or negative event, the algorithm maintains separate event counters, POS_COUNT and NEG_COUNT. ADD_VAL and SUB_VAL programmed values are the same for both event counters.

On each sensor sample, the event counters, POS_COUNT and NEG_COUNT, are updated based on the SAF_TH comparators. Likewise, each event counter is compared with a corresponding arming threshold. In this case, POS_COUNT value is compared to ARMP_TH and NEG_COUNT to ARMN_TH. ARMP_TH and ARMN_TH are programmable thresholds set by the user. The compared result will set ARMP and ARMN to either '1' or '0' depending on the comparison status. If ARMP_TH or ARMN_TH are set to 0, the arming will be activated immediately entering in safing state.

POS_COUNT and NEG_COUNT are not updated if microcontroller stops reading SAF_CC bits (this must be avoided otherwise ARMING set and reset will not be possible).

By way of the assignment of the ADD_VAL, SUB_VAL, ARMP_TH and ARMN_TH settings, the safing engine can be configured to assert arming for either a simple accumulation of COUNTs in a non-consecutive manner, or it could be set to require some number of consecutive samples.

12.5 Safing engine output logic (ARMxINT)

SPI messages are monitored and mapped to specific safing records. Each safing record is configured with its own threshold, dwell time and the appropriate ARMxINT signal to activate if safing criteria are met.

Any enabled safing record can be programmed to an arming signal. All safing records arming status is logically 'OR'd' to its programmed arming signal. For example, if safing records 1, 2, 4 are programmed to ARMINT1 and the records are enabled, any of the records can set the ARMINT1 signal. Configuration of safing record mapping to ARMXINT signals is specified in the in the SAF_CONTROL_x register (refer to *Table 67*).

While in Diag state, L9680 allows diagnostics of the squib driver HS and LS FETs, ARM pins, VSF output and firing timers. The ARM and VSF output tests are mutually exclusive.

For safety purposes, the safing logic circuitry is physically separated from the circuitry that contains the deployment logic.

Figure 60. Safing engine arming flow diagram

Figure 61. Safing engine diagnostic logic

A configurable mask for each internal ARMxINT signal is available for all of the integrated deployment loops. The un-masked ARMxINT signal for each loop will enable the respective loop drivers.

Activation of VSF (regulation rail for High Side Safing FET) occurs upon ARMxINT. Actual High Side Safing FET activation still requires microcontroller signal.

L9680 is able to provide arming signals to external deployment loops by means of four discrete output ARMx pins.

Figure 62. ARMx input/output control logic

12.5.1 Arming pulse stretch

Upon a valid command processed by the safing logic, the Dwell bit to stretch the arming time assertion (dwell time) applies to each safing record and is used to help safe the deployment sequence to avoid undesired behaviour.

Once dwell time has started, it will continue, regardless of the En (Record Enable) bit. Dwell will be truncated in case of SSM reset. Dwell values in the safing records are transferred to the ARMx signals. A dedicated counter is designed for each ARMx output pin. If different dwell values are assigned to the same ARMx, the longer value is used. Dwell times can only be extended, not reduced. If the remaining dwell time is less than the new dwell extension setting, the new setting will be loaded into the dwell counter.

Dwell times are user programmable.

The behaviour of the pulse stretch timer is shown below.

Figure 63. Pulse stretch timer example

The Arming Enable Pulse Stretch Timer status is available in the AEPSTS register.

12.6 Additional communication line

The ACL pin is the Additional Communication Line input that provides a means of safely activating the arming outputs (ARMx and VSF) for disposal of restraints devices at the end of vehicle life.

The handshake sequence for activating the Arming outputs is illustrated in Figure 64. The strategy involves generation of a seed value from within the L9680 device using a freerunning 8-bit counter running at f_{SCRAP SEED} rate, where it can be read by the microcontroller. The microcontroller uses it to generate an 8-bit key value. When the seed value is read (SPI SCRAP_SEED command), L9680 also freezes the seed value and computes its own key, which is used for comparison to the key subsequently submitted by the microcontroller. The key value is submitted by the microcontroller using the SCRAP_KEY command, and successful reception of this command with a key value matching the internally calculated key allows the successful completion of the first handshake. After that, in case a second handshake (seed-key) completes successfully and if a valid ACL is detected (as described below) the L9680 transitions from Scrap state to Arming state. To remain in Arming state the microcontroller must periodically refresh L9680 with the SCRAP KEY command containing the correct key value in the data field of the command, and L9680 must also receive the correct ACL signal. This must occur before the scrap timeout timer expires (T_{SCRAP TIMEOUT}). The scrap key is derived from the seed value using a simple logical inversion on the even-numbered bits (0, 2, 4, 6). From a logical standpoint, this is equivalent to a bit-wise XOR of the seed value with 0x55.

While the SSM is in Arming state, the arming outputs are asserted (ARMx=1, VSF on). If the periodic scrap key is incorrect, or not received before the timeout expires, or the ACL is not correctly received, the SSM reverts back to the Scrap state, and the arming outputs are deactivated.

Figure 64. Scrap SEED-KEY state diagram

Figure 65. Scrap ACL state diagram

DS11615 Rev 2

A specific waveform needs to be present on ACL input in order to instruct L9680 to arm all deployment loops. L9680 is designed to support the Additional Communication Line (ACL) aspect of the ISO-26021 standard, which requires an independent hardwired signal (ACL) to implement the scrapping feature. The disposal signal may come from either the vehicle's service connector, or the systems main microcontroller, depending on the end customer's requirements.

The arming function monitors the disposal PWM input (ACL pin) for a command to arm all loops for vehicle end-of-life airbag disposal. The disposal signal characteristic is shown in *Figure 66*. To remain in Arming state, at least three cycles of the ACL signal must be qualified (in addition to the periodic KEY value being received from the microcontroller). For the device to qualify the periodic ACL signal, the period and duty cycle are checked. Two consecutive cycles of invalid disposal signal are to be received to disqualify the ACL signal.

If the logic detects that the signal is incorrect or missing while in Scrap state, the device will stay in Scrap state; would it happen in Arming state, it will transition to Scrap state immediately.

Figure 66. Disposal PWM signal

The disposal PWM signal cycle time and on time parameters can be found in the electrical parameters tables.

13 General purpose output (GPO) drivers

The L9680 contains three General Purpose Output (GPO) drivers configurable either as high-side or low-side modes. The drivers can be independently controlled in ON-OFF mode or in PWM mode setting the desired duty cycle value through the GPO Control Register (GPOCTRLx).

For low side driver configuration, the GPODx pin is the drain connection of an internal MOSFET and is the current sink for the output driver. The GPOSx pin is the source connection of the internal MOSFET and is externally connected to ground. For high side driver configuration, the GPODx pin will be connected to battery and GPOSx pin will be connected to load's high side.

Figure 67. GPO driver and diagnostic block diagram

The drivers are configured in one of the two modes through the GPO Configuration Register (GPOCR) register. This hardware configuration is only allowed during the Init and Diag states.

When configured as high-side, the drivers need ER Boost voltage to be above the $V_{\text{ERBST}\ OK}$ threshold to be enabled.

The default state of all drivers is off. The drivers can be independently activated via SPI control bits on GPO Control Register (GPOCTRLx). In addition, a set point on the GPOCTRLx will control the output drivers in PWM with a 125Hz frequency. If PWM control is desired, user should set the needed set point in the GPOxPWM bits of the GPOCTRLx while activating the interface. When all bits are set to '0', the GPOx output will be disabled.

DS11615 Rev 2

PWM control is based on a 125Hz frequency. 6 bits of GPOCTRLx are reserved to this mode, in order to control the drivers with 64 total levels from a 0% to a full 100% duty cycle.

When both GPO channels are used in PWM Mode at the same frequency they are synchronized to provide parallel configuration capability.

PWM control is implemented through a careful slew rate control to mitigate EMC emissions while operating the interface. The driver output structure is designed to stand -1V on its terminals and a +1V reverse voltage across source and drain.

The GPO driver is protected against short circuits and thermal overload conditions. The output driver contains diagnostics available in the GPO Fault Status Register (GPOFLTSR). All faults except for thermal overload will be latched until the GPOFLTSR register is read. Thermal overload faults will remain active after reading the GPOFLTSR register should the temperature remain above the thermal fault condition. For current limit faults, the output driver will operate in a linear mode (ILIM) until a thermal fault condition is detected.

Figure 68. GPO Over temperature logic

The device offers also an open load diagnostics while in ON state. The diagnostics is run comparing the current through the output stage with a reference threshold $I_{OpenLoad}$: should the output current be lower than the threshold, the open detection flag is asserted.

The device is also able to detect a fault condition during the OFF state by means of the Voltage Regulator Current Monitor (VRCM) block. During the OFF state the VRCM block tries to force a voltage $V_{OUT_GPOx_OL}$ (2.5 V) on GPOD pin if LS mode is selected (with a current limitation of $I_{LIM_GPOD_SRC/SINK}$) or on GPOS pin if the HS mode is selected (with a current limitation of $I_{LIM_GPOS_SRC/SINK}$) and, at the same, it compares the current sourced or sunk in order to detect if a fault on GPO pins is present. The diagnostic in OFF state is able to detect the open load in both HS and LS modes, the short to ground fault in LS mode and the short to battery fault in HS mode:

| | LS MODE | | | | |
|--|-----------|------------|-----------------|--|--|

System voltage diagnostics 14

L9680 has an integrated dedicated circuitry to provide diagnostic feedback and processing of several inputs. These inputs are addressed with an internal analog multiplexer and made available through the SPI digital interface with the Diagnostic Data commands. In order to avoid saturation of high voltage internal signals, an internal voltage divider is used.

Figure 69. ADC MUX

The diagnostics circuitry is activated by four SPI Diagnostics Control commands (DIAGCTRLx); each of them can address all the available nodes to be monitored, except for what mentioned in Table 18.

DIAGCTRLx SPI command bit fields are structured in the following way:

DIAGCTRL_A (ADDRESS HEX 3A)

| | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

| MISO | NEWDATA_D | 0 | 0 | | A | DCR | EQ_ | D [6 | :0] | | | | | | ADC | RES_I | D [9:0] | | | |

ADCREQ[A-D] bit fields, used to address the different measurements offered, are listed in *Table 18* for reference.

L9680 diagnostics is structured to take four automatic conversions at a time. In order to get four measurements, four different SPI commands have to be sent (DIAGCTRL_A, DIAGCTRL_B, DIAGCTRL_C and DIAGCTRL_D), in no particular order.

In case the voltage to be measured is not immediately available, the desired inputs for conversion have to be programmed by SPI in advance, to allow them to attain a stable voltage value. This case applies to the squib resistance measurement and diagnostics (refer to *Loop diagnostics control and results registers*) and to the DC sensor measurement (refer to *Section 11*).

CONVRDY_0 bit in GSW is equal to (NEWDATA_A or NEWDATA_B), while CONVRDY_1 bit in GSW corresponds to (NEWDATA_C or NEWDATA_D).

Each NEWDATAx flag is asserted when conversion is finished and cleared when result is read out. However result is cleared only when new result for that register is available.

When a new request is received it is queued if other conversions are ongoing. The conversions are executed in the same order as their request arrived. The queue is 4 measures long so it's possible to send all 4 requests at the same time and then wait for the results. If a DIAGCTLRx command is received twice, the second conversion request will overwrite the previous one.

Requests are sent to the L9680 IC via the ADC measurement Registers (ADCREQx) as shown in *Table 18*. All diagnostics results are available on the ADCRESx registers, when addressed by the related ADCREQx register (e.g. data requested by ADCREQA would be written to ADCRESA).

Table 19. Diagnostics divider ratios (continued)

For measurements other than voltage (current, resistance, temperature etc.) the ranges are specified in the electrical parameters section of the relevant block.

14.1 Analog to digital algorithmic converter

The device hosts an integrated 10 bit Analog to Digital converter, running at a clock frequency of 16 MHz. The ADC output is processed by a D to D converter with the following functions:

- Use of trimming bits to recover additional gain error due to resistor dividers mismatch;
- Digital low-pass filtering;
- Conversion from 12 to 10 bits.

10 bits data are filtered inside the digital section. The number of samples that are filtered vary depending on the chosen conversion. As per *Section 7.3.2*, the number of used samples in converting DC sensor, squib or temperature measurements defaults to 8. The number of samples for all other measurements defaults to 4. The sample number can be configured by accessing the SYS_CFG register. After low pass filter, the residual total error is ± 4 LSB. This error figure applies to the case of a ideal reference voltage: the spread of reference voltage causes a proportional error in the conversion output. The reference voltage of the ADC is set to 2.5 V.

The conversion time is comprised of several factors: the number of measurements loaded into the queue, the number of samples taken for any one measurement, and the various settling times. An example of conversion time calculation for a full ADC request queue is reported in *Figure 70*. The timings reported in *Figure 70* are nominal ones, min/max values can be obtained by considering the internal oscillator frequency variation reported in the DC characteristics section.

Figure 70. ADC conversion time

15 Temperature sensor

The L9680 provides an internal analog temperature sensor. The sensor is aimed to have a reference for the average junction temperature on silicon surface. The sensor is placed far away from power dissipating stages and squib deployment drivers. The output of the temperature sensor is available via SPI through ADC conversion, as shown in *Table 18*. The formula to calculate temperature from ADC reading is the following one:

$$T(^{\circ}C) = 180 - \left\{ \left(\frac{220}{1.652}\right) \cdot \left[\left(\frac{ADC_{REF}}{2} \cdot DIAGCTRLn(ADCRESn)\right) - 0.739 \right] \right\}$$

@ DIAGCTRLn(ADCREQn) = 0A_{hex}

All parametric requirements for this block can be found in specification tables.

16 Electrical characteristics

Every parameter in this chapter is fulfilled down to VIN_{GOOD(max)}.

No device damage is granted to occur down to $\text{VIN}_{\text{BAD}}(\text{min}).$

GNDA pin is used as ground reference for the voltage measurements performed within the device, unless otherwise stated.

All table or parameter declared 'Design Info' are not tested during production testing

16.1 Configuration and control

All electrical characteristics are valid for the following conditions unless otherwise noted. -40 °C \leq Ta \leq +95 °C.

| No | Symbol | Parameter | Conditions | Min | Тур | Max | Unit |
|----|---------------------|------------------------------|---|------|------|------|------|
| 1 | V _{NOV} | Normal Operating Voltage | Design Info Depending on power supply configuration | 6 | 13 | 18 | V |

| 9 | R _{RATIO_10} | resistance | Multiplexer input to GNDA | 160 | - | - | kΩ |
| 10 | R _{RATIO_15} | | Multiplexer input to GNDA | 200 | - | - | kΩ |
| 11 | ILEAK_MUX_ON | Additional multiplexer on-state input leakage current | For all divider ratio expect ratio_1 | _ | - | 60 | μA |
| 12 | V _{MEAS_ACC} | Voltage measurement accuracy | (±15LSB) plus divider error (±3%) | | | | |

16.24 **Temperature sensor**

All electrical characteristics are valid for the following conditions unless otherwise noted:

40 °C \leq Ta \leq +95 °C, VIN_{GOOD0} \leq VIN \leq 35 V.

| | Table 72. Temperature sensor specifications | | | | | | | | |
|----|---|---------------------------------|------------|-----|-----|-----|------|--|--|
| No | Symbol | Parameter | Conditions | Min | Тур | Max | Unit | | |
| 1 | T _{MON_RANGE} | Monitoring temperature range | - | -40 | - | 150 | °C | | |
| 2 | T _{MON_ACC} | Monitoring temperature accuracy | - | -15 | - | 15 | °C | | |

17 Quality information

17.1 OTP memory

The device contains a 128-bits One-Time Programmable memory. This OTP memory is used for the following purposes:

- 1. 86 bits data + 3 bits CRC for critical parameters trimming: bandgaps, oscillators, reference currents, firing currents, DC sensor and RSU interface parameters.
- 2. 18 bits data for other blocks trimming: ADC, ER Cap Measurement
- 3. 20 bits data for die and wafer traceability
- 4. 1 bit for debug purpose

User read/write access to the OTP memory via SPI is only possible during production testing and require activation of a special test mode.

During mission mode, the trimming bits are automatically read from OTP and transferred to the related circuits at each POR cycle. During this operation, actual CRC of the protected trimming data is calculated and checked against the expected CRC stored in the OTP. In case of CRC check failure the OTPCRC_ERR flag is set in the FLTSR register.

18 Errata sheet

Table 73. Errata sheet

| L9680CC | | |
|---------|----------------------------------|---|
| | Deployment Diagnostic | The high side driver diagnostic, described in section <i>on page 173</i> , doesn't work. As consequence, the I _{LIM_HS_FET} parameter is not tested in production. |
| L9680CC | WSS Over current detection | The over current threshold doesn't work. The user can use the leakage to ground flag to understand if a fault condition is present. The interface is anyway protected by means of thermal protection. |
| | | The safing records associated with CS_RS validate and process data with matching request/response masks even if these are not coming from CS_RS frames but from frames sniffed on SAF_CSx. |
| L9680CC | Safing engine | This may lead to issues when expansion chip is used and CS_RS frames sent on expansion are sniffed by SAF_CSx at SBC side; the SBC fails to check its own CS_RS and therefore all RSUs safing records CC with matching request/response masks of expansion RSUs safing records will be updated upon the processing of the expansion RSU SPI data. Workaround: use two different values for WID SPI bit when addressing CS_RS at SBC (ie WID=1) and expansion (WID=0) |
| | | L9680CC current detection |

19 Package information

In order to meet environmental requirements, ST offers these devices in different grades of ECOPACK[®] packages, depending on their level of environmental compliance. ECOPACK[®] specifications, grade definitions and product status are available at: *www.st.com*. ECOPACK[®] is an ST trademark.

ИНН 7805602321 КПП 780501001 Р/С 40702810122510004610 ФАКБ "АБСОЛЮТ БАНК" (ЗАО) в г.Санкт-Петербурге К/С 3010181090000000703 БИК 044030703

Компания «Life Electronics» занимается поставками электронных компонентов импортного и отечественного производства от производителей и со складов крупных дистрибьюторов Европы, Америки и Азии.

С конца 2013 года компания активно расширяет линейку поставок компонентов по направлению коаксиальный кабель, кварцевые генераторы и конденсаторы (керамические, пленочные, электролитические), за счёт заключения дистрибьюторских договоров

Мы предлагаем:

- Конкурентоспособные цены и скидки постоянным клиентам.
- Специальные условия для постоянных клиентов.
- Подбор аналогов.
- Поставку компонентов в любых объемах, удовлетворяющих вашим потребностям.
- Приемлемые сроки поставки, возможна ускоренная поставка.
- Доставку товара в любую точку России и стран СНГ.
- Комплексную поставку.
- Работу по проектам и поставку образцов.
- Формирование склада под заказчика.
- Сертификаты соответствия на поставляемую продукцию (по желанию клиента).
- Тестирование поставляемой продукции.
- Поставку компонентов, требующих военную и космическую приемку.
- Входной контроль качества.
- Наличие сертификата ISO.

В составе нашей компании организован Конструкторский отдел, призванный помогать разработчикам, и инженерам.

Конструкторский отдел помогает осуществить:

- Регистрацию проекта у производителя компонентов.
- Техническую поддержку проекта.
- Защиту от снятия компонента с производства.
- Оценку стоимости проекта по компонентам.
- Изготовление тестовой платы монтаж и пусконаладочные работы.
