## GENERAL DESCRIPTION

The AD6459 is a 3 V , low power receiver IF subsystem for operation at input frequencies as high as 500 MHz and IFs from 5 MHz up to 50 MHz . It is optimized for operation in GSM, DCS1800 and PCS1900 receivers. It consists of a mixer, an IF amplifier, I and Q demodulators, a phase-locked quadrature oscillator, a precise AGC subsystem, and a biasing system with external power-down.
The AD6459's low noise, high intercept mixer is a doublybalanced Gilbert-Cell type. It has a nominal -11 dBm inputreferred 1 dB compression point and a 0 dBm input-referred third-order intercept. The mixer section of the AD6459 also includes a local oscillator (LO) preamplifier, which lowers the required LO drive to -16 dBm .
The gain control input accepts an external gain-control voltage input from an external AGC detector or a DAC. It provides an 80 dB gain range with $27 \mathrm{mV} / \mathrm{dB}$ gain scaling.
The I and Q demodulators provide in-phase and quadrature baseband outputs to interface with Analog Devices' AD7013

## REV. 0

[^0]FUNCTIONAL BLOCK DIAGRAM

(IS54, TETRA, MSAT) AD7015 and AD6421 (GSM, DCS1800, PCS1900) baseband converters. An on-board quadrature VCO that is externally phase-locked to the IF signal drives the I and Q demodulators. This locked reference signal is normally provided by an external VCTCXO under the control of the radio's digital processor. The AD6459 can also provide demodulation of N-PSK and N-QAM in many non-TDMA systems when used with external analog carrier recovery systems such as the Costas Loop. Finally, the VCO can be phase-locked to a frequency that is deliberately offset from the IF as in the case of a Beat-Frequency oscillator ( BFO ) resulting in the product detection of CW or SSB.

The AD6459 uses supply voltages from 2.7 V to 5.5 V over the temperature range of $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$. Operation is enabled by a CMOS logical level; response time is typically $<80 \mu \mathrm{~s}$. When disabled, the standby current is reduced to $2 \mu \mathrm{~A}$.
The AD6459 comes in a 20-pin shrink small outline (SSOP) surface mount package.

## CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD6459 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

## AD6459

## PRODUCT OVERVIEW

The AD6459 provides most of the active circuitry required to realize a complete low power, single-conversion superheterodyne receiver, or the latter part of a double-conversion receiver, at input frequencies up to 500 MHz , with an IF from 5 MHz to 50 MHz . The internal I/Q demodulators, and their associated phase-locked loop, support a wide variety of modulation modes, including n-PSK, n-QAM and GMSK. A single positive supply voltage of 3 V is required ( 2.7 V minimum, 5.5 V maximum) at a typical supply current of 8 mA at midgain. In the following discussion, $\mathrm{V}_{\text {POS }}$ will be used to denote the power supply voltage, which will be normally assumed to be 3 V .
Figure 20 shows the main sections of the AD6459. It consists of a variable-gain UHF mixer and a linear two-stage IF strip, which together provide a calibrated voltage-controlled gain range of more than 76 dB , followed by dual quadrature demodulators. These are driven by inphase and quadrature clocks that are generated by a Phase-Locked Loop (PLL), which is locked to a corrected external reference. A CMOS-compatible power-down interface completes the AD6459.

## Mixer

The UHF mixer is an improved Gilbert-cell design and can operate from low frequencies (it is internally dc-coupled) up to an RF input of 500 MHz . The dynamic range at the input of the
mixer is determined, at the upper end, by the maximum input signal level of $\pm 90 \mathrm{mV}(-11 \mathrm{dBm}$ in $50 \Omega$ between RFHI and RFLO) up to which the mixer remains essentially linear, and at the lower end, by the noise level. It is customary to define the linearity of a mixer in terms of its 1 dB gain-compression point and third-order intercept, which for the AD6459 are -11 dBm and 0 dBm , respectively, in a $50 \Omega$ system.

The mixer's RF input port is differential; that is, pin RFLO is functionally identical to RFHI, and these nodes are internally biased. The RF port can be modeled as a parallel RC circuit as shown in Figure 19.

Figure 19. Mixer Port Modeled as a Parallel RC Network
The local oscillator (LO) input is internally biased at $\mathrm{V}_{\mathrm{P}}-0.8 \mathrm{~V}$ and must be ac coupled. The LO interface includes a preamplifier that minimizes the drive requirements, thus simplifying the oscillator design and reducing LO leakage from the RF port. The LO requires a single-sided drive of $\pm 50 \mathrm{mV}$, or -16 dBm in a $50 \Omega$ system. For operation above 300 MHz , noise figure can be improved by increasing the LO level.

Figure 20. Functional Block Diagram

The output of the mixer is differential. The nominal conversion gain is specified for operation into a 19.5 MHz LC IF bandpass filter as shown in Figure 21 and Table I.
The conversion gain is measured between the mixer input and the input of this filter and varies between -5 dB and +15 dB .

Figure 21. Suggested IF Filter Inserted Between the Mixer's Output Port and the Amplifier's Input Port

Table I. Filter Component Values for Selected Frequencies

| Frequency | C1 | L1 | C2 |
| :--- | :--- | :--- | :--- |
| 13 MHz | 27 pF | $0.82 \mu \mathrm{H}$ | 180 pF |
| 19.5 MHz | 27 pF | $0.56 \mu \mathrm{H}$ | 110 pF |
| 26 MHz | 22 pF | $0.39 \mu \mathrm{H}$ | 82 pF |
| 40 MHz | 22 pF | $0.12 \mu \mathrm{H}$ | 100 pF |

The maximum permissible signal level between MXOP and MXOM is determined by the maximum gain control voltage.
The mixer output port, having pull-up resistors of $250 \Omega$ to $\mathrm{V}_{\mathrm{POS}}$, is shown in Figure 22.

Figure 22. Mixer Output Port

## IF Amplifier

Most of the gain in the AD6459 is provided by the IF amplifier strip, which comprises two stages. Both are fully differential and each has a gain span of 26 dB for the AGC voltage range of 0.2 V to 2.25 V . Thus, in conjunction with the variable gain of the mixer, the total gain span is 76 dB . The overall IF gain varies from -13 dB to 45 dB for the nominal AGC voltage of 0.2 V to 2.25 V . Maximum gain is at $\mathrm{V}_{\text {GAIN }}=0.2 \mathrm{~V}$.

The IF input is differential, at IFIP and IFIM. Figure 23 shows a simplified schematic of the IF interface modeled as parallel RC network.

The IF's small-signal bandwidth is approximately 50 MHz from IFIP and IFIM through the demodulator.

Figure 23. IF Amplifier Port Modeled as a Parallel RC Network

## Gain Scaling

The AD6459's overall gain, expressed in decibels, is linear with respect to the AGC voltage $\mathrm{V}_{\text {GAIN }}$ at pin GAIN. The gain of all sections is maximum when $\mathrm{V}_{\text {GAIN }}$ is 0.2 V and falls off as the bias is increased to $\mathrm{V}_{\text {GAIN }}=2.25 \mathrm{~V}$. The gain is independent of the power supply voltage. The gain of all stages changes simultaneously. The AD6459's gain scaling is also temperature compensated.
Note that GAIN pin of the AD6459 is an input driven by an external low impedance voltage source, normally a DAC, under the control of the radio's digital processor.
The gain-control scaling is directly proportional to the reference voltage applied to the pin GREF and is independent of the power supply voltage. When this input is set to the nominal value of 1.2 V , the scale is nominally $27 \mathrm{mV} / \mathrm{dB}(37 \mathrm{~dB} / \mathrm{V})$. Under these conditions, 76 dB of gain range (mixer plus IF) corresponds to a control voltage of $0.2 \mathrm{~V} \leq \mathrm{V}_{\mathrm{GAIN}} \leqq 2.25 \mathrm{~V}$. The final centering of this 2.05 V range depends on the insertion losses of the IF filters used.

Pin GREF can be tied to an external voltage reference ( $\mathrm{V}_{\mathrm{REF}}$ ) provided, for example, by an AD1580 (1.21 V) voltage reference.
When using the Analog Devices AD7013 (IS54, TETRA, and satellite receiver applications) and AD7015 or AD6421 (GSM, DCS1800, PCS1900) baseband converters, the external reference may also be provided by the reference output of the baseband converters. The interface between the AD6459 and the AD6421 baseband converter is shown in Figure 24. The AD7015 baseband converter provides a $V_{R}$ of 1.23 V . An auxiliary DAC in the AD7015 can be used to generate the AGC voltage. Since it uses the same reference voltage, the numerical input to this DAC provides an accurate RSSI value in digital form, no longer requiring the reference voltage to have high absolute accuracy.

Figure 24. Interfacing the AD6459 to the AD6421 Baseband Converter

## AD6459

## I/Q Demodulators

Both demodulators (I and Q ) receive their inputs internally from the IF amplifiers. Each demodulator comprises a full-wave synchronous detector followed by an 8 MHz , two-pole low-pass filter, producing differential outputs at pins IRXP and IRXN, and QRXP and QRXN. Using the I and Q demodulators for IFs above 50 MHz is precluded by the 5 MHz to 50 MHz range of the PLL used in the demodulator section.
The I and Q outputs are differential and can swing up to 2.2 V p-p at the low supply voltage of 2.7 V . They are nominally centered at 1.5 V , independent of power supply. They can therefore directly drive the RX ADCs in the AD7015 baseband converter, which require an amplitude of 1.23 V to fully load them when driven by a differential signal. The conversion gain of the I and Q demodulators is 17 dB .
For IFs of less than 8 MHz , the on-chip low-pass filters $(8 \mathrm{MHz}$ cutoff) do not adequately attenuate the IF or feedthrough products; thus, the maximum input voltage must be limited to allow sufficient headroom at the I and Q outputs for not only the desired baseband signal but also the unattenuated higherorder demodulation products. These products can be removed by an external low-pass filter. A simple 1-pole RC filter with its corner above the modulation bandwidth is sufficient to attenuate undesired outputs. The design of the RC filter is eased by the $4.7 \mathrm{k} \Omega$ resistor integrated at each I and Q output pin.

## Phase-Locked Loop

The demodulators are driven by quadrature signals that are provided by a variable-frequency quadrature oscillator (VFQO), phase-locked to a reference signal applied to pin FREF. When this signal is at the IF, inphase and quadrature baseband outputs are generated at the I output (IRXP and IRXN) and Q output (QRXP and QRXN), respectively. The quadrature accuracy of this VFQO is typically within $\pm 1.5^{\circ}$ at 19.5 MHz . A simplified diagram of the FREF input is shown in Figure 25.

Figure 25. Simplified Schematic of the FREF interface The VFQO operates from 5 MHz to 50 MHz and is controlled by the voltage between VPOS and FLTR. In normal operation a series RC network, forming the PLL loop filter, is connected from FLTR to $\mathrm{V}_{\text {POs. }}$. The use of an integral sample-hold system ensures that the frequency-control voltage on pin FLTR remains held during power-down, so reacquisition of the carrier occurs in less than $80 \mu \mathrm{~s}$.
In practice, the probability of a phase mismatch at power-up is high, so the worst case linear settling period to full lock needs to be considered in making filter choices. This is typically $<80 \mu \mathrm{~s}$ for a quadrature phase error of $\pm 3^{\circ}$ at an IF of 19.5 MHz . Note that
the VFQO always provides quadrature between its own $I$ and Q outputs, but the phasing between it and the reference carrier will swing around the final value during the PLL's settling time.

## Bias System

The AD6459 operates from a single supply ( $\mathrm{V}_{\mathrm{POS}}$ ) usually 3 V , at a typical supply current of 8 mA at midgain and $\mathrm{T}_{\mathrm{A}}=+25^{\circ} \mathrm{C}$, corresponding to a power consumption of 24 mW . Any voltage from 2.7 V to 5.5 V may be used.
The bias system includes a fast-acting active high CMOScompatible power-up switch, allowing the part to idle at $2 \mu \mathrm{~A}$ when disabled. Biasing is generally proportional-to-absolutetemperature (PTAT) to ensure stable gain with temperature. Other special biasing techniques are used to ensure very accurate gain, stable over the full temperature range.

## USING THE AD6459

In this section, we will focus on a few areas of special importance and include a few general application tips. As with any wideband high gain component, great care is needed in PC board layout. The location of the particular grounding points must be considered with due regard to the possibility of unwanted signal coupling.
The high sensitivity of the AD6459 leads to the possibility that unwanted local EM signals may have an effect on the performance. During system development, carefully-shielded test assemblies should be used. The best solution is to use a fully enclosed box enclosing all components with the minimum number of needed signal connectors (RF, LO, I and Q outputs) in miniature coax form.

## Gain Distribution

As with all receivers, the most critical decisions in effectively using the AD6459 relate to the partitioning of gain between the various subsections (Mixer, IF Amplifier/Demodulator) and the placement of filters to achieve the highest overall signal-to-noise ratio and lowest intermodulation distortion.
Figure 26 shows an example of the main RF/IF signal path at maximum and minimum signal levels.

## AD6459

## AD6459 EVALUATION BOARD

The AD6459 evaluation board（Figure 27）consists of a AD6459，ground plane，I／O connectors，and a 19.5 MHz band pass filter．The RF，LO and FREF ports are terminated in $50 \Omega$ to provide a broadband match or external signal generators．
The board provides SMA connectors for the RF，LO，demodu－ lator reference，mixer output and IF input signals．The MXOP and IFIP connectors are left unconnected and are provided as a testing convenience．Footprints for broadband matching trans－ formers and matching components are also provided to aid in stage breakout testing．
The remaining low frequency signals，including the I and Q interface，bias and power connections are made via a dual row pin header that acts as an Interface Connector located along the edges of the board．An on－board gain－reference 1.2 V biasing option is provided via a single jumper，J1．The evaluation board will not function without this jumper unless an external bias GREF is provided from an external reference that is normally provided by the associated ADC．

## Full Path Configuration

As received，the board is configured for full－path evaluation from RFHI to the I and Q outputs．The one－pole LC resonant circuit provided represents a simple，yet balanced，IF bandpass filtering approach．The filter supplied is centered at 19.5 MHz ， a common GSM intermediate frequency．Table I highlights the filter component values for other IF frequencies．RFHI and RFLO are true differential inputs，however for testing conve－ nience，the RFLO terminal of the AD6459 is ac referenced to ground on the evaluation board．The GAIN bias input，which is bypassed with a 10 nF capacitor，is brought out to the interface connector．The PRUP input is provided with a $20 \mathrm{k} \Omega$ pull up resistor to $\mathrm{V}_{\text {POS }}$ that activates the board．

The four differential I and Q outputs are brought out uncondi－ tioned，directly to the interface connector．A high impedance， high bandwidth FET－type probe should be used when measur－ ing the I and Q ports．Excessive capacitive or resistive loading of these ports will severely limit the video bandwidth and signal swing．The demodulator PLL filter installed on the evaluation board（R8，C10）can accommodate the full VFQO lock range specified．

## OUTLINE DIMENSIONS

Dimensions shown in inches and（mm）．

LifeElectronics
Живое партнерство

Компания «Life Electronics» занимается поставками электронных компонентов импортного и отечественного производства от производителей и со складов крупных дистрибьюторов Европы, Америки и Азии.

С конца 2013 года компания активно расширяет линейку поставок компонентов по направлению коаксиальный кабель, кварцевые генераторы и конденсаторы (керамические, пленочные, электролитические), за счёт заключения дистрибьюторских договоров

Мы предлагаем:

- Конкурентоспособные цены и скидки постоянным клиентам.
- Специальные условия для постоянных клиентов.
- Подбор аналогов.
- Поставку компонентов в любых объемах, удовлетворяющих вашим потребностям.
- Приемлемые сроки поставки, возможна ускоренная поставка.
- Доставку товара в любую точку России и стран СНГ.
- Комплексную поставку.
- Работу по проектам и поставку образцов.
- Формирование склада под заказчика.
- Сертификаты соответствия на поставляемую продукцию (по желанию клиента).
- Тестирование поставляемой продукции.
- Поставку компонентов, требующих военную и космическую приемку.
- Входной контроль качества.
- Наличие сертификата ISO.

В составе нашей компании организован Конструкторский отдел, призванный помогать разработчикам, и инженерам.

Конструкторский отдел помогает осуществить:

- Регистрацию проекта у производителя компонентов.
- Техническую поддержку проекта.
- Защиту от снятия компонента с производства.
- Оценку стоимости проекта по компонентам.
- Изготовление тестовой платы монтаж и пусконаладочные работы.
