## MAX20303

## PMIC with Ultra Low I<sub>Q</sub> Voltage Regulators, Battery Charger and Fuel Gauge for Small Lithium Ion Systems

### General Description

The MAX20303 is a highly integrated and programmable power management solution designed for ultra-low-power wearable applications. It is optimized for size and efficiency to enhance the value of the end product by extending battery life and shrinking the overall solution size. A flexible set of power-optimized voltage regulators, including multiple bucks, boost, buck-boost, and linear regulators, provides a high level of integration and the ability to create a fully optimized power architecture. The quiescent current of each regulator is specifically suited for 1μA (typ) to extend battery life in always-on applications.

The MAX20303 includes a complete battery management solution with battery seal, charger, power path, and fuel gauge. Both thermal management and input protection are built into the charger.

The device also includes a factory programmable button controller with multiple inputs that are customizable to fit specific product UX requirements.

Three integrated LED current sinks are included for indicator or backlighting functions, and an ERM/LRA driver with automatic resonance tracking is capable of providing sophisticated haptic feedback to the user.

The device is configurable through an I<sup>2</sup>C interface that allows for programming various functions and reading device status, including the ability to read temperature and supply voltages with the integrated ADC.

This device is available in a 56-bump, 0.5mm pitch 3.71mm x 4.21mm, wafer-level package (WLP) and operates over the -40°C to +85°C extended temperature range.

### Applications

- Wearable Devices
- IoT

**Ordering Information** appears at end of data sheet.

### Benefits and Features

- Extend Battery Use Time Between Battery Charging
  - 2 x Micro-I<sub>Q</sub> Buck Regulators (<1μA I<sub>Q</sub> (typ) Each)
    - 220mA Output
    - Buck1: 0.8V to 2.375V in 25mV Steps
    - Buck2: 0.8V to 3.95V in 50mV Steps
  - Micro-I<sub>Q</sub> LV LDO/Load Switch (1μA I<sub>Q</sub> (typ))
    - 1.16V to 2.0V Input Voltage
    - 50mA Output
    - 0.5V to 1.95V Output, 25mV Steps
  - Micro-I<sub>Q</sub> LDO/Load Switch (1μA I<sub>Q</sub> (typ))
    - 1.71V to 5.5V Input Voltage
    - 100mA Output
    - 0.9V to 4V, 100mV Steps
  - Micro-I<sub>Q</sub> Buck-Boost Regulator (1.3μA I<sub>Q</sub> (typ))
    - 250mW Output
    - 2.5V to 5V in 100mV Steps
- Easy-to-Implement Li+ Battery Charging
  - Wide Fast Charge Current Range: 5mA to 500mA
  - Smart Power Selector
    - 28V/-5.5V Tolerant Input
    - Programmable JEITA Current/Voltage Profiles
- Minimize Solution Footprint Through High Integration
  - Safe Output LDO
    - 15mA When CHGIN Present
    - 5V or 3.3V
  - Haptic Driver
    - ERM/LRA Driver with Quick Start And Breaking
    - Automatic Resonance Tracking (LRA only)
- Support Wide Variety of Display Options
  - Micro-I<sub>Q</sub> Boost Regulator (2.4μA I<sub>Q</sub> (typ))
    - 300mW Output
    - 5V to 20V in 250mV Step
  - 3 Channel Current Sinks
    - 20V Tolerant
    - Programmable from 0.6 to 30mA
- Optimize System Control
  - Power-On/Reset Controller
  - Programmable Push-Button Controller
  - Programmable Supply Sequencing
  - Factory Shelf Mode
  - On-Chip Voltage Monitor Multiplexer and Analog-to-Digital Converter (ADC)

## Absolute Maximum Ratings

BAT, SYS, MON, PFN1, PFN2, THM, INT,  $\overline{\text{RST}}$ ,  
SDA, SCL, CELL, ALRT, CTG, QSTRT, L2IN,  
BBOUT ..... -0.3V to +6V  
VDIG, L1IN ..... -0.3V to +2.2V  
CHGIN ..... -6V to +30V  
CAP, SFOUT ..... -0.3V to min(|CHGIN| + 0.3, +6)V  
TPU ..... -0.3V to VDIG + 0.3V  
SET ..... -0.3V to BAT + 0.3V  
MPC0, MPC1, MPC2, MPC3, MPC4, DRP,  
DRN, BK1LX, BK2LX, BK1OUT, BK2OUT,  
CPP, BSTLVLX, BBLVLX ..... -0.3V to SYS + 0.3V  
L1OUT ..... -0.3V to L1IN + 0.3V  
L2OUT ..... -0.3V to L2IN + 0.3V  
CPP ..... CPN – 0.3V to CPN + 6V  
CPOUT ..... CPP – 0.3V to min(CPP + 6, +12)V  
BSTHVLX, BSTOUT, LED0, LED1, LED2 ..... -0.3V to +22V

BSTHVLX to BSTOUT ..... -22V to +0.1V  
BBHVLX ..... -0.3V to min(BBOUT + 0.3, +6)V  
AGND, DGND, BK1GND, BK2GND, BSTGND,  
HDGND, BBGND to GSUB ..... -0.3V to +0.3V  
Continuous Current into BAT, SYS ..... -1000mA to +1000mA  
Continuous Current into CHGIN ..... -1mA to +1000mA  
Continuous Current into DRP, DRN ..... -600mA to +600mA  
Continuous Current into Any Other Terminal -100mA to +100mA  
Continuous Power Dissipation (multilayer board  
at +70°C): 7 x 8 Array 56-Ball, 3.71mm x  
4.21mm, 0.5mm pitch WLP (derate 29.98mW/°C) ..... 2399mW  
Operating Temperature Range ..... -40°C to +85°C  
Junction Temperature ..... +150°C  
Storage Temperature Range ..... -65°C to +150°C  
Lead Temperature (soldering, 10s) ..... +300°C  
Soldering Temperature (reflow) ..... +260°C

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## Package Information

|---------------------------------------------|---------------------------------------|
| <b>PACKAGE TYPE: 56 WLP</b>                 |                                       |
| Package Code                                | W563A4+1                              |
| Outline Number                              | <b>21-100104</b>                      |
| Land Pattern Number                         | Refer to <b>Application Note 1891</b> |
| <b>THERMAL RESISTANCE, FOUR-LAYER BOARD</b> |                                       |
| Junction to Ambient ( $\theta_{JA}$ )       | 33.35°C/W                             |

For the latest package outline information and land patterns (footprints), go to [www.maximintegrated.com/packages](http://www.maximintegrated.com/packages). Note that a "+", "#", or "-" in the package code indicates RoHS status only. Package drawings may show a different suffix character, but the drawing pertains to the package regardless of RoHS status.

Package thermal resistances were obtained using the method described in JEDEC specification JESD51-7, using a four-layer board. For detailed information on package thermal considerations, refer to [www.maximintegrated.com/thermal-tutorial](http://www.maximintegrated.com/thermal-tutorial).

| Spike Pulse Widths Suppressed by Input Filter    | t <sub>SP</sub>     |                                             | 50  |     |     | ns    |

**Note 1:** All devices are 100% production tested at T<sub>A</sub> = +25°C. Limits over the operating temperature range are guaranteed by design.

**Note 2:** V<sub>CCINT</sub> is an internal voltage supply generated from either V<sub>BAT</sub> or V<sub>CAP</sub>. The source is determined by the following:

IF [(V<sub>CHGIN</sub> > V<sub>CHGIN\_DET</sub> AND V<sub>CAP</sub> > V<sub>CAP\_OK</sub>) OR V<sub>CAP</sub> > (V<sub>BAT</sub> + V<sub>THSWOVER</sub>)]

THEN V<sub>CCINT</sub> = V<sub>CAP</sub>

ELSE

V<sub>CCINT</sub> = V<sub>BAT</sub>

Where V<sub>THSWOVER</sub> = [0-300]mV

**Note 3:** All voltages are referenced to GND.

**Note 4:** Test performed on unmounted/unsoldered parts.

**Note 5:** The voltage is trimmed and verified with 16x averaging.

**Note 6:** Fuel Gauge enters shutdown mode after SCL < V<sub>IL</sub> and SDA < V<sub>IL</sub> for longer than t<sub>SLEEP</sub>.

**Note 7:** Guaranteed by design.

## Typical Operating Characteristics

$V_{BAT} = +3.7V$ ,  $C_{SFOUT} = 1\mu F$ ,  $C_{VDIG} = 1\mu F$ ,  $C_{CAP} = 1\mu F$ ,  $C_{SYS} = 10\mu F$ ,  $C_{BK1OUT\_EFF} = 15\mu F$ ,  $C_{BK2OUT\_EFF} = 10\mu F$ ,  $C_{L1IN} = 22\mu F$ ,  $C_{L2IN} = 22\mu F$ ,  $C_{L1OUT\_EFF} = 15\mu F$ ,  $C_{L2OUT\_EFF} = 10\mu F$ ,  $C_{CPP} = 27nF$ ,  $C_{BSTOUT\_EFF} = 10\mu F$ ,  $C_{BBOUT\_EFF} = 10\mu F$ ,  $L_{BK1} = 2.2\mu H$ ,  $L_{BK2} = 2.2\mu H$ ,  $L_{BSTOUT} = 4.7\mu H$ ,  $L_{BBOUT} = 4.7\mu H$ ,  $T_A = +25^\circ C$ , unless otherwise noted.

## Bump Configuration

## Bump Description

| BUMP   | NAME   | FUNCTION                                                                                                                                                                              |
|--------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| A1     | DRN    | ERM/LRA Haptic Driver Negative Output.                                                                                                                                                |
| A2     | DRP    | ERM/LRA Haptic Driver Positive Output.                                                                                                                                                |
| A3     | HDGND  | Haptic Driver Ground.                                                                                                                                                                 |
| A4, H4 | SYS    | System Load Connection. Connect to the system load. Both SYS bumps should be connected on PCB through a low-impedance trace. Bypass common node with a minimum 10μF capacitor to GND. |
| A5     | L2OUT  | LDO Output. Bypass with 1μF capacitor to GND.                                                                                                                                         |
| A6     | BK2GND | Buck 2 Ground.                                                                                                                                                                        |
| A7     | BK2LX  | Buck2 Regulator Switch. Connect through 2.2μH inductor to BK2OUT.                                                                                                                     |
| B1     | SCL    | I <sup>2</sup> C Serial Clock Input.                                                                                                                                                  |
| B2     | SDA    | I <sup>2</sup> C Serial Data Input/Open-Drain Output.                                                                                                                                 |
| B3     | CPP    | Charge Pump Capacitor Positive Terminal. Connect 22nF (min), 33nF (max) capacitor to CPN.                                                                                             |
| B4     | CPN    | Charge Pump Capacitor Negative Terminal. Connect to 22nF (min), 33nF (max) capacitor to CPP.                                                                                          |
| B5     | CPOUT  | Charge Pump Output. Bypass with 1μF capacitor to GND.                                                                                                                                 |
| B6     | L2IN   | LDO2 Input. Bypass with 1μF capacitor to GND.                                                                                                                                         |
| B7     | BK2OUT | Buck2 Regulator Output. Bypass with 10μF capacitor to GND.                                                                                                                            |
| C1     | LED2   | Current Sink Output 2.                                                                                                                                                                |
| C2     | DGND   | Digital Ground.                                                                                                                                                                       |
| C3     | MPC4   | Multipurpose Control I/O 4.                                                                                                                                                           |
| C4     | MPC1   | Multipurpose Control I/O 1.                                                                                                                                                           |
| C5     | MPC0   | Multipurpose Control I/O 0.                                                                                                                                                           |
| C6     | CELL   | Fuel Gauge Voltage. Bypass with 0.1μF capacitor to GND.                                                                                                                               |
| C7     | BBOUT  | Buck-Boost Regulator Output. Bypass with 10μF capacitor to GND.                                                                                                                       |
| D1     | LED1   | Current Sink Output 1.                                                                                                                                                                |
| D2     | PFN1   | Configurable Power Mode Control Pin (e.g., $\overline{\text{KIN}}$ ).                                                                                                                 |
| D3     | GSUB   | Substrate Connection. Connect to Ground.                                                                                                                                              |

## Bump Description (continued)

| BUMP | NAME    | FUNCTION                                                                                                                                                                        |
|------|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| E6   | ALRT    | Fuel Gauge Alert Output.                                                                                                                                                        |
| E7   | BBHVLX  | Buck-Boost Regulator Switch HV side. Connect through a 3.3μH or 4.7μH inductor to BBLVLX.                                                                                       |
| F1   | BSTOUT  | Boost Regulator Output. Bypass with 10μF capacitor to GND.                                                                                                                      |
| F2   | SFOUT   | Safe Out LDO. Bypass with 1μF capacitor to GND.                                                                                                                                 |
| F3   | SET     | External Resistor For Battery Charge Current Level Setting. Do not connect any capacitance on this pin; maximum allowed capacitance ( $C_{SET} < 5\mu s/R_{SET}$ )pF.           |
| F4   | TPU     | Battery Temperature Thermistor Measurement Pullup (Internally Connected To V <sub>DI</sub> G During Battery Temperature Thermistor Measurement). Do not exceed 1mA load on TPU. |
| F5   | THM     | Battery Temperature Thermistor Measurement Connection.                                                                                                                          |
| F6   | RST     | Reset Output. Active-Low, Open-Drain Output.                                                                                                                                    |
| F7   | BBLVLX  | Buck-Boost Regulator Switch LV Side. Connect through a 3.3μH or 4.7μH inductor to BBHVLX.                                                                                       |
| G1   | BSTGND  | High-Voltage Boost Ground.                                                                                                                                                      |
| G2   | INT     | Interrupt Open-Drain Output.                                                                                                                                                    |
| G3   | MPC3    | Multipurpose Control I/O 3.                                                                                                                                                     |
| G4   | MPC2    | Multipurpose Control I/O 2.                                                                                                                                                     |
| G5   | L1OUT   | LDO1 Output. Bypass with 1μF capacitor to GND.                                                                                                                                  |
| G6   | L1IN    | LDO1 Input. Bypass with 1μF capacitor to GND.                                                                                                                                   |
| G7   | BK1OUT  | Buck1 Regulator Output. Bypass with 10μF capacitor to GND.                                                                                                                      |
| H1   | BSTHVLX | Boost Regulator Switch. Connect through a 4.7μH inductor to BSTLVLX.                                                                                                            |
| H2   | BSTLVLX | Boost Regulator Switch. Connect through a 4.7μH inductor to BSTHVLX.                                                                                                            |
| H3   | BAT     | Battery Connection. Connect to positive battery terminal. Bypass with a minimum 1μF capacitor to GND.                                                                           |
| H5   | CHGIN   | +28V/-5.5V Protected Charger Input. Bypass with 1μF capacitor to GND.                                                                                                           |
| H6   | BK1GND  | Buck 1 Ground.                                                                                                                                                                  |
| H7   | BK1LX   | Buck1 Regulator Switch. Connect through a 2.2μH inductor to BK1OUT.                                                                                                             |

**Note:** All capacitance values listed in this document refer to effective capacitance. Be sure to specify capacitors that will meet these requirements under typical operating conditions taking into consideration the effects of voltage and temperature.

### Typical Application Diagram

## Detailed Description

### Power Regulation

The MAX20303 features two high-efficiency, low quiescent current buck regulators, a buck-boost regulator, a high-voltage boost regulator, a charge pump, and two low quiescent current, low-dropout (LDO) linear regulators that are configurable as load switches. Additionally, a safe-output LDO is available when there is a valid voltage present at CHGIN. This SFOUT regulator's output is configurable to 3.3V or 5V. Excellent light-load efficiency allows the switching regulators to run continuously without significant energy cost. The buck and boost regulators can operate in a fixed peak current mode for low-current applications, as well as an adaptive peak current mode to improve load regulation, extend the high-efficiency range, and minimize capacitor size when more current is required.

### Power Switch and Reset Control

The MAX20303 features a power switch that provides the ability to execute a reset sequence or to turn off the main system power and enter Off mode to extend battery life.

Shutdown and reset events are triggered by an external control through the power function (PFN) control inputs, I<sup>2</sup>C commands, or if other conditions are met. The behavior of the PFN pins is preconfigured to support one of the multiple types of wearable application cases. [Table 1](#) describes the behavior of the PFN1 and PFN2 pins based on the PwrRstCfg[3:0] bits, while [Figure 1a](#) thru [Figure 1d](#) shows basic flow diagrams associated with each mode. Both PFN pins have a 10ms debounce period to distinguish valid inputs followed by a PwrRstCfg dependent timing to execute the PFN function.

A soft reset sends a 10ms pulse on  $\overline{\text{RST}}$  and will either leave register settings unchanged or reset them to their default values depending on the device version (see [Table 192](#) for device settings). A hard reset on any device initiates a complete Power-On Reset sequence.

The device enters Off mode on cold boot (initial battery attach, V<sub>CHGIN</sub> = 0V) in response to a power-off I<sup>2</sup>C command, a valid PFN signal based on the PwrRstCfg[3:0] setting, or in the case of a UVLO condition on SYS. When the device is in Off mode, the BAT-SYS connection is opened and all functions are disabled except for the power function controller and LDO2 (if configured as always-on).

The MAX20303 will exit Off mode and turn the main power back on when there is a qualified PFN1 signal (PwrRstCfg[3:0] = 0000, 0001, 0110, 0111, 1000) or when a valid voltage is applied to CHGIN. In the powered-on state, the SYS node is enabled and other functions can be controlled through the I<sup>2</sup>C registers. When the power-on event occurs, the BAT-to-CELL switch is immediately closed and, 30ms later, the power path to SYS is enabled. This delay allows the fuel gauge to take an open cell measurement before the battery is loaded. Note that there is a relearning period to determine the state of the battery whenever the fuel gauge is disconnected. If the typical use case frequently switches the fuel gauge off and on, the user may consider permanently connecting CELL-to-BAT to avoid the relearning period. [Figure 2](#) illustrates a complete boot sequence coming out of the Off state.

PwrRstCfg = 0000, 0001

Figure 1a. PwrRstCfg = 0000 or 0001

On mode through $\overline{\text{KIN}}$ long-press (3s) or CHGIN insertion. Soft reset through PFN2 long press (12s).                                                                                                       |
| 1001-1111 | RFU                                                          |                                                              |                                                                                                                                                                                                                                                                              |

\* See [Table 193](#) for default PFN1 and PFN2 configurations.

Figure 2. The full MAX20303 Boot Sequence

Power Sequencing

The sequencing of the switching regulators, LDOs, and charge pump during power-on is configurable. See each regulator’s sequencing bits for details. Regulators can turn on at one of three points during the power-on process: 75ms after the power-on event, at the time the  $\overline{\text{RST}}$  signal is released, or at two points in between. The two points between SYS and  $\overline{\text{RST}}$  are fixed proportionally to the duration of the Power-On Reset (POR) process ( $t_{\text{RST}}$ ). The timing relationship is presented graphically in [Figure 3](#).

Alternatively, the regulators can remain off by default and turn on with an I<sup>2</sup>C command after  $\overline{\text{RST}}$  is released.

LDO2 can be configured to be always-on as long as SYS or BAT is present.

The SYS voltage is monitored during the power-on sequence. If  $V_{\text{SYS}}$  falls below  $V_{\text{SYS\_UVLO\_F}}$  during the sequencing process with a valid voltage at CHGIN, the process repeats from the point where SYS was enabled to allow more time for the voltage to stabilize. If there is not a valid voltage at CHGIN, the device returns to the OFF state to avoid draining the battery. Power is also turned off if BAT experiences a current greater than  $I_{\text{BAT\_OC\_R}}$  for more than  $t_{\text{BAT\_OC\_D}}$ .

Figure 3. Reset Sequence Programming

## Current Sink

In addition to several voltage regulators, the MAX20303 also includes three low-dropout linear current regulators from LED<sub>-</sub> to GND. The sink current of each current regulator is independently programmable through its respective LED\_ISet[4:0] bits in direct registers LED\_Direct (0x2D–0x2F). The current regulators can be programmed to sink 0.6mA to 30mA with configurable step sizes and are ideal for sinking current from external LEDs. The LEDStep[1:0] bits in direct register LEDStepDirect (0x2C) control the size of the current steps for all current sinks. This step size also sets an effective limit on the sinking current as the number of steps remains constant while the step size varies. Current sinks are enabled through an I<sup>2</sup>C command, by an internal charger status signal, or by an external MPC pin allowing for LED status indicators. Note that the current sinks always draw quiescent current when tied to an MPC<sub>-</sub> control or status signal regardless of the MPC<sub>-</sub> or status state.

## System Load Switch

An internal 80mΩ (typ) MOSFET connects BAT to SYS when no voltage source is available on CHGIN. When an external source is detected at CHGIN, this switch opens and SYS is powered from the input source through the input current limiter. The SYS-to-BAT switch also prevents V<sub>SYS</sub> from falling below V<sub>BAT</sub> when the system load exceeds the input current limit. If V<sub>SYS</sub> drops to V<sub>BAT</sub> due to the current limit, the BAT-SYS switch turns on so the load is supported by the battery. If the system load continuously exceeds the input current limit, the battery is not charged. This is useful for handling loads that are nominally below the input current limit but have high current peaks exceeding the input current limit. During these peaks, battery energy is used, but at all other times the battery charges.

## Smart Power Selector

The smart power selector seamlessly distributes power from the external CHGIN input to the BAT and SYS nodes. With both an external adapter and battery connected, the smart power selector basic functions are:

- When the system load requirements are less than the input current limit, the battery is charged with residual power from the input.
- When the system load requirements exceed the input current limit, the battery supplies supplemental current to the load.
- When the battery is connected and there is no external power input, the system is powered from the battery.

## Input Limiter

The input limiter distributes power from the external adapter to the system load and battery charger. In addition to the input limiter's primary function of passing power to the system load and charger, it performs several additional functions to optimize use of available power.

**Invalid CHGIN Voltage Protection:** If CHGIN is above the overvoltage threshold, the device enters overvoltage lockout (OVL). OVL protects the MAX20303 and downstream circuitry from high-voltage stress up to +28V and down to -5.5V. During positive OVL, the internal circuit remains powered and an interrupt is sent to the host. The negative voltage protection disconnects CHGIN and the device is powered only by BAT. The charger turns off and the system load switch closes, allowing the battery to power SYS. CHGIN is also invalid if it is less than V<sub>BAT</sub>, or less than the USB undervoltage threshold. With an invalid input voltage, the BAT-SYS load switch closes and allows the battery to power SYS.

**CHGIN Input Current Limit:** The CHGIN input current is limited to prevent input overload. The input current limit is controlled by I<sup>2</sup>C. To accommodate systems with a high in-rush current, the limiter includes a programmable blanking time during which the input current limit increases to I<sub>LIM\_MAX</sub>.

**Thermal Limiting:** In case the die temperature exceeds the normal limit (T<sub>CHG\_LIM</sub>), the MAX20303 attempts to limit temperature increase by reducing the input current from CHGIN. In this condition, the system load has priority over the charger current, so the input current is first reduced by lowering the charge current. If the junction temperature continues to rise and reaches the maximum operating limit (T<sub>CHGIN\_SHDN</sub>), no input current is drawn from CHGIN and the battery powers the entire system load.

**Adaptive Battery Charging:** While the system is powered from CHGIN, the charger draws power from SYS to charge the battery. If the total load exceeds the input current limit, an adaptive charger control loop reduces charge current to prevent V<sub>SYS</sub> from collapsing. When the charge current is reduced below 50% due to I<sub>LIM</sub> or T<sub>CHG\_LIM</sub> limits, the timer clock operates at half speed. When the charge current is reduced below 20% due to I<sub>LIM</sub> or T<sub>CHG\_LIM</sub> limits, the timer clock is paused.

**Fast-Charge Current Setting:** The MAX20303 uses an external resistor connected from SET to GND to set the fast-charge current. The precharge and charge-termination currents are programmed as a percentage of this value by opcode 0x14. The fast-charge current resistor can be calculated as:

$$R_{SET} = K_{SET} \times V_{SET} / I_{FChg}$$

where  $K_{SET}$  has a typical value of 2000A/A and  $V_{SET}$  has a typical value of +1V. The range of acceptable resistors for  $R_{SET}$  is 4kΩ to 400kΩ.

A capacitive load on SET can cause instability of the charger if the condition  $(C_{SET} < 5\mu s/R_{SET})$  pF is violated.

### SAR ADC/Monitor MUX

In order to simplify system monitoring, the MAX20303 includes a voltage monitor multiplexer (MUX). The I<sup>2</sup>C controlled MUX connects the MON pin to the scaled value of one of six voltage regulators, BAT, or SYS. A resistive divider scales the voltage to one of four ratios determined by MONRatioCfg[1:0] (opcode 0x50, [Table 117](#)). Because the MUX can only tolerate voltages up to +5.5V,  $V_{CHGIN}$ ,  $V_{CPOUT}$ , and  $V_{BSTOUT}$  are not available to MON.

An internal ADC reads the remaining voltage rails and performs system tasks such as JEITA temperature monitoring and SYS tracking during haptic driver operations. Manual ADC measurements are initiated by writing the desired channel to ADC\_Measure\_Launch (opcode 0x53, [Table 121](#)) and reading the response from APDataIn0-3. The ADC can also measure the MON voltage when the MUX is enabled with a 1:1 ratio. The full-scale range of the ADC for different voltage rails is detailed in [Table 2](#).

### JEITA Monitoring with Charger Control

To enhance safety when charging Li+ batteries, the MAX20303 includes JEITA-compliant temperature monitoring. A resistive divider is formed on THM by attaching a pullup resistor to TPU and connecting the thermistor of a battery-pack (do not exceed 1mA load on TPU). The divider output is read by the internal ADC when JEITA monitoring is enabled and the resulting temperature measurement places the battery into one of

**Table 2. SAR ADC Full-Scale Voltages and Conversions**

| VOLTAGE RAIL  | AVAILABLE RANGE      | CONVERSION (V)           |
|---------------|----------------------|--------------------------|
| <b>SYS</b>    | +2.6V to +5.5V       | (Result[7:0] * 5.5)/255  |
| <b>MON</b>    | 0V to +5.5V          | (Result[7:0] * 5.5)/255  |
| <b>THM</b>    | 0% to 100% $V_{DIG}$ | (Result[7:0] * 100)/255  |
| <b>CHGIN</b>  | +3V to +8V           | (Result[7:0] * 8.25)/255 |
| <b>CPOUT</b>  | +3V to +8V           | (Result[7:0] * 8.25)/255 |
| <b>BSTOUT</b> | +3V to +21V          | (Result[7:0] * 21.0)/255 |

five temperature zones: cold, cool, room, warm, and hot. Zone-specific temperature limits and charging behavior are fully configurable through the ChargerThermalLimits\_Config\_Write (opcode 0x16, [Table 69](#)) and ChargerThermalReg\_Config\_Write (opcode 0x18, [Table 73](#)) commands detailed in [Table 69](#) and [Table 73](#). Some example profiles are included in [Figure 4](#). It is important to note that, because battery temperature is measured by the internal ADC, JEITA monitoring is unavailable when automatic level compensation is enabled in the haptic driver.

### Haptic Driver

The MAX20303 features a versatile, integrated haptic driver. The driver allows for real time control of haptic devices through PWM or I<sup>2</sup>C as well as the ability to run haptic patterns from internal RAM. For added flexibility, the driver is capable of driving both Linear Resonant Actuator (LRA) and Eccentric Rotating Mass (ERM) actuators.

Figure 4a. Sample JEITA Pre Charge Profile

Figure 4b. Sample JEITA Fast Charge Profile

Figure 4c. Sample JEITA Maintain Charge Profile

Figure 5. Charger State Diagram

**ERM**

An ERM is the simplest haptic actuator to drive. The driving signal is taken directly as the output of an integrated H-bridge, allowing for bidirectional operation of the actuator. To configure the MAX20303 to drive an ERM, the HptSel bit must be set to 0 using the opcode 0xA0 or 0xAD ([Table 127](#) and [Table 153](#)).

**LRA**

Unlike the on-off control of an ERM, LRAs require a sinusoidal driving signal. The MAX20303 realizes this with a Class-D amplifier that converts the driver input to a sinusoidal output. Note that any changes made to the output amplitude take effect in the next period of the sinusoid.

An LRA's vibration magnitude is maximized when the driving signal matches the LRA's resonant frequency. To ensure the haptic driver closely tracks this frequency, the MAX20303 includes an auto-resonance tracking feature. Resonance tracking is enabled by setting the EmfEn bit to 1 with opcode 0xA0 or 0xAD. The range of resonant frequencies that can be reliably driven is 120Hz to 305Hz. Enabling resonance tracking is strongly recommended when driving an LRA to ensure maximum driving efficiency and amplitude.

To select LRA mode, set the HptSel bit to 1 using opcode 0xA0 or 0xAD.

**Driver Amplitude**

The haptic driver features a configurable voltage basis for the amplitude of the driving signal. Setting this basis, referred to as the full-scale voltage ( $V_{FS}$ ), configures the maximum amplitude of the driver output. It is set using HptVfs[7:0] with opcode 0xA2 or 0xB2 ([Table 131](#) and [Table 163](#)) and has a range of 0V to 5.5V (LSB = 21.57mV). Since the H-bridge is supplied by  $V_{SYS}$ , the actual full-scale voltage of the driver at any given moment is the minimum of the value stored in HptVfs[7:0] and  $V_{SYS}$ .

Once  $V_{FS}$  has been set, all driver amplitudes are scaled as a percentage of the full-scale voltage. The resolution of the amplitude is always  $V_{SYS}/128$ . Therefore, the effective resolution of the amplitude scales with the  $V_{FS}/V_{SYS}$  ratio. For example, if  $V_{FS} = V_{SYS}/2$ , the effective resolution is 6 bits.

**Automatic Level Compensation**

Because  $V_{SYS}$  can vary over time, the driver must adjust its output duty cycle to maintain a constant reference to the full-scale voltage. An Automatic Level Compensation (ALC) function measures  $V_{SYS}$  and handles this adjustment. ALC can be enabled by setting the AlcMod bit to 1 using opcode

0xA0 or 0xAD and uses the MAX20303's internal ADC to monitor  $V_{SYS}$ . The ALC function then scales the haptic driver's duty cycle as needed to maintain the programmed driver amplitude. If ALC is not enabled,  $V_{SYS}$  is assumed to be  $V_{FS}$ .

**Haptic UVLO**

Additionally,  $V_{SYS}$  is measured after the driver is enabled but prior to starting a vibration. At any moment, if  $V_{SYS}$  goes below the programmed UVLO value, which is set through HptSysUVLO[7:0] with opcode 0xA6 ([Table 139](#)), the vibration event is aborted and the haptic driver is locked. See the [Haptic Driver Lock](#) section for details regarding restarting vibration if a haptic UVLO condition is reached.

The time required to perform the  $V_{SYS}$  measurement, as well as other startup delays, results in an initial latency of the haptic driver. To avoid partial pattern skipping in real-time modes, vibration patterns should be provided at least t<sub>HD\_START</sub> after enabling the desired real-time vibration mode (PPWM or RTI<sup>2</sup>C).

**Vibration Timeout**

A vibration timeout parameter is programmable through I<sup>2</sup>C. If a vibration lasts longer than the programmed timeout period, the vibration is aborted. The timeout period is stored in HptDrvTmo[5:0] (LSB = 1s), which can be written using opcode 0xB7 ([Table 173](#)). Writing code "000000" disables the timeout function. See the [Haptic Driver Lock](#) section for details regarding restarting vibration if a timeout is reached.

**Overcurrent/Thermal Protection**

The haptic driver also includes overcurrent and thermal shutdown protection. While the haptic driver is active, the MAX20303 monitors the current from DRP and DRN. If overcurrent protection is enabled (HptOCProtDis = 0) and the DRP or DRN current exceeds I<sub>HD\_OC\_THR</sub>, the haptic driver issues a fault, aborts vibration, and enters the locked state.

Thermal protection allows the MAX20303 to immediately shut down the haptic driver should the die temperature exceed T<sub>HD\_OC\_THR</sub>. This feature is enabled by setting HptThmProtDis = 0.

See the [Haptic Driver Lock](#) section for details regarding restarting vibration if an overcurrent or overtemperature condition is reached.

**Haptic Driver Lock**

If the MAX20303 detects a fault in the haptic driver, vibrations in progress are aborted and the haptic driver is locked by the HptLock bit. The user must manually clear the HptLock bit using opcode 0xA8 (Table 143) in order to run a new vibration attempt. A fault occurs under any of the following conditions:  $V_{SYS}$  drops below the threshold programmed in HptSysUVLO[7:0] (SystemError 0x25), an overcurrent is detected on DRN or DRP (SystemError = 0x20, 0x21, 0x22, or 0x23), the die temperature exceeds the thermal protection threshold (SystemError = 0x24), or a vibration duration exceeds the timeout period stored in HptDrvTmo[5:0] (SystemError 0x04). Writing any value other than 0x00 with opcode 0xA8 will set HptLock high and disable the driver output.

**Interface Modes**

There are a total of four interface modes for controlling the haptic driver. These include two real-time modes and two stored memory modes. The haptic driver mode is set through HptDrvMode[4:0] with the direct-access I<sup>2</sup>C register 0x31. Selecting an operation mode also enables the driver. In addition, HptDrvEn must be set and kept to 1 before setting HptDrvMode[4:0] and for the whole duration of vibration. Once vibration finishes, HptDrvMode[4:0] must be set to “00000” before the haptic driver may be disabled via HptDrvEn = 0 for power savings.

**Pure-PWM (PPWM)**

PPWM mode offers real-time control of the haptic driver. Patterns are generated by applying a PWM signal to the MPC\_ pin selected by HptDrvMode[4:0]. The duty cycle of the applied signal determines the amplitude of the driving signal, scaled by  $V_{FS}$ . The driving direction is centered about a 50% duty cycle. A duty cycle of 0% to 47.5% produces a (100 to 0)% $V_{FS}$  amplitude in the negative direction and a duty cycle of 52.5% to 100% produces a (0 to 100)% $V_{FS}$  amplitude in the positive direction. The region between 47.5% and 52.5% duty cycle is a dead zone and inputs within this range correspond to a null output.

A timeout feature prevents idle PWM inputs from causing unwanted vibrations of the haptic motor. If the input signal remains at 0% duty cycle or 100% duty cycle for more than 2.56ms, the output is null and vibration stops. As such, the MPC\_ input must remain dynamic to produce a continuous output.

**Real-Time I<sup>2</sup>C (RTI<sup>2</sup>C)**

Similar to PPWM mode, RTI<sup>2</sup>C mode offers real-time control of the haptic driver. The direct register HptRTI2CAmp (0x32) determines the amplitude of the output signal. The lower seven bits of the register (HptRTI2CAmp[6:0]) set the amplitude as a percentage of  $V_{FS}$  and the MSB (HptRTI2CSign) sets the direction of rotation. 100% amplitude, reverse drive, for example, is produced by setting HptRTI2CAmp to 0x7F (0b01111111).

Once RTI<sup>2</sup>C mode is enabled through HptDrvMode[4:0], the haptic driver continuously outputs the amplitude and direction defined by the latest data in HptRTI2CAmp. In order to generate haptic patterns, the HptRTI2CAmp register must receive new data.

**External Triggered Stored Pattern (ETRG)**

In ETRG mode, a rising edge on an MPC\_ pin or a 0-to-1 transition of the HptExtTrig bit in direct I<sup>2</sup>C register 0x31 initiates a vibration sequence. The sequence is contained in six registers and comprises an overdrive (startup) amplitude, active drive amplitude, braking amplitude, and the duration of each driving behavior.

Amplitudes contained in ETRGOdAmp[7:0], ETRGActAmp[7:0], and ETRGBrkAmp[7:0], which are set through opcode 0xA2–0xA4 or 0xB3 (Table 131 thru Table 136 and Table 165), follow the same format as HptRTI2CSign + HptRTI2CAmp[6:0] in direct I<sup>2</sup>C register 0x32 (i.e., the lower-seven bits store the amplitude as a percentage of  $V_{FS}$  and the MSB determines the direction).

The trigger input is selected when the driver enters ETRG mode via HptDrvMode[4:0] in direct I<sup>2</sup>C register 0x31. In order to properly register the rising edge, the trigger signal must remain high for a few clock cycles of the driver. Once the sequence begins, the haptic driver follows the duration values stored in ETRGOdDur[7:0], ETRGActDur[7:0], and ETRGBrkDur[7:0]. It is possible, however, to extend the active drive time by leaving the trigger high longer than the time specified in ETRGActDur[7:0]. Doing so will cause the driver to output the amplitude stored in ETRGActAmp[7:0] until a falling edge is detected. Once the trigger signal falls low, the brake sequence executes.

**RAM Stored Haptic Pattern (RAMHP)**

The final method of controlling the haptic driver is RAMHP mode. The MAX20303 contains an internal 256 x 24 bit RAM in which haptic patterns are stored. By storing haptic sequences in RAM at startup, the driver can perform sophisticated haptic sequences upon receipt of a trigger signal as in ETRG mode. The direct I<sup>2</sup>C register HptPatRAMAddr (0x33) specifies the RAM address where the sequence begins.

MAX20303

PMIC with Ultra Low I<sub>Q</sub> Voltage Regulators,  
Battery Charger and Fuel Gauge  
for Small Lithium Ion Systems

RAM should be loaded when the MAX20303 comes out of Off mode. To write data to the RAM, the HptRAMEn bit in direct register HptDirect1 (0x31) must first be set high. Next, writing a value to the direct register HptRAMAddr (0x28) specifies the RAM address in which data written to HptDataH, HptDataM, and HptDataL (0x29, 0x2A, and 0x2B, respectively) is stored. It is possible to read back data from RAM. Writing an address to HptRAMAddr, then initiating an I<sup>2</sup>C read transaction of register 0x29, will allow readback of the three bytes stored in the RAM address. RAM read and write procedures are depicted graphically in [Figure 6](#).

A haptic pattern is composed of multiple pattern samples. Pattern samples define the amplitude, duration, wait time, transition, and repetition of a segment of a haptic pattern.

These samples are defined in three bytes and written to RAM through HptDataH, HptDataM, and HptDataL. HptDataH contains the sign of the sample's amplitude (AxSign), the upper-five bits of the amplitude (Ax[6:2]), and instructions to the haptic driver on handling the pattern sample (nLSx). HptDataM contains the lower two bits of the sample's amplitude (Ax[1:0]), the duration of the sample (Dx), and the upper bit of the wait time before the next sample in the pattern (Wx[4]). HptDataL contains the lower four bits of the wait time (Wx[3:0]) and the repetition behavior (RPTx). [Table 3](#) describes the definition of a pattern sample and [Figure 7](#) provides a sample haptic pattern with corresponding waveform.

Fuel Gauge

ModelGauge Theory of Operation

The MAX20303 fuel gauge is based on the MAX17048 stand-alone fuel gauge and simulates the internal, non-linear dynamics of a Li+ battery to determine its State of Charge (SOC). The sophisticated battery model considers impedance and the slow rate of chemical reactions in the battery. ModelGauge performs best with a custom model, obtained by characterizing the battery at multiple discharge currents and temperatures to precisely model it. At power-on reset (POR), the ICs have a preloaded ROM model that performs well for some batteries. For more details on the fuel gauge, refer to the MAX17048 data sheet.

Fuel-Gauge Performance

In coulomb counter-based fuel gauges, SOC drifts because offset error in the current-sense ADC measurement accumulates over time. Instantaneous error can be very

small, but never precisely zero. Error accumulates over time in such systems (typically, 0.5%–2% per day) and requires periodic corrections. Some algorithms correct drift using occasional events and, until such an event occurs, the algorithm’s error is boundless:

- Reaching predefined SOC levels near full or empty
- Measuring the relaxed battery voltage after a long period of inactivity
- Completing a full charge/discharge cycle

ModelGauge requires no correction events because it uses only voltage, which is stable over time. The ModelGauge remains accurate despite the absence of any of the above events; it neither drifts nor accumulates error over time.

To correctly measure performance of a fuel gauge as experienced by end-users, exercise the battery dynamically. Accuracy cannot be fully determined from only simple cycles.

**Battery Voltage and State of Charge**

Open-circuit voltage (OCV) of a Li+ battery uniquely determines its SOC; one SOC can have only one value of OCV. In contrast, a given V<sub>CELL</sub> can occur at many different values of OCV because V<sub>CELL</sub> is a function of time, OCV, load, temperature, age, impedance, etc.; one value of OCV can have many values of V<sub>CELL</sub>. Therefore, one SOC can have many values of V<sub>CELL</sub>, so V<sub>CELL</sub> cannot uniquely determine SOC.

Even the use of sophisticated tables to consider both voltage and load results in significant error due to the load transients typically experienced in a system. During charging or discharging, and for approximately 30 min after, V<sub>CELL</sub> and OCV differ substantially, and V<sub>CELL</sub> has been affected by the preceding hours of battery activity. ModelGauge uses voltage comprehensively.

**Temperature Compensation**

For best performance, the host microcontroller must measure battery temperature periodically, and compensate the RCOMP ModelGauge parameter accordingly, at least once per minute. Each custom model defines constants RCOMP0 (0x97, default), TempCoUp (-0.5, default), and TempCoDown (-5.0, default). To calculate the new value of CONFIG.RCOMP:

```
// T is battery temperature (degrees Celsius)
if (T > 20) {
    RCOMP = RCOMP0 + (T - 20) x TempCoUp;
}
else {
    RCOMP = RCOMP0 + (T - 20) x TempCoDown;
}
```

**Impact of Empty-Voltage Selection**

Most applications have a minimum operating voltage below which the system immediately powers off (empty voltage). When characterizing the battery to create a custom model, choose empty voltage carefully. Capacity unavailable to the system increases at an accelerating rate as empty voltage increases.

To ensure a controlled shutdown, consider including operating margin into the fuel gauge based on some low threshold of SOC, for example shutting down at 3% or 5%. This utilizes the battery more effectively than adding error margin to empty voltage.

**Battery Insertion**

When the battery is first inserted into the system, the fuel-gauge IC has no previous knowledge about the battery's SOC. Assuming that the battery is relaxed, the IC translates its first V<sub>CELL</sub> measurement into the best initial estimate

of SOC. Initial error caused by the battery not being in a relaxed state diminishes over time, regardless of loading following this initial conversion. While SOC estimated by a coulomb counter diverges, ModelGauge SOC converges, correcting error automatically. Initial error has no long-lasting impact.

**Battery Insertion Debounce**

Any time the IC powers on or resets (see the [VRESET/ID Register \(0x18\)](#) section), it estimates that OCV is the maximum of 16 V<sub>CELL</sub> samples (1ms each, full 12-bit resolution). OCV is ready 17ms after battery insertion, and SOC is ready 175ms after that.

**Battery Swap Detection**

If V<sub>CELL</sub> falls below V<sub>RST</sub>, the IC quick-starts once V<sub>CELL</sub> returns above V<sub>RST</sub>. This handles battery swap; the SOC of the previous battery does not affect that of the new one. See the [Quick-Start](#) and [VRESET/ID Register \(0x18\)](#) sections.

**Quick-Start**

If the IC generates an erroneous initial SOC, the battery insertion and system power-up voltage waveforms must be examined to determine if a quick-start is necessary, as well as the best time to execute the command. The IC samples the maximum V<sub>CELL</sub> during the first 17ms. See the [Battery Insertion Debounce](#) section. Unless V<sub>CELL</sub> is fully relaxed, even the best sampled voltage can appear greater or less than OCV. Therefore, quick-start must be used cautiously.

Most systems should not use quick-start because the ICs handle most startup problems transparently, such as intermittent battery-terminal connection during insertion. If battery voltage stabilizes faster than 17ms, do not use quick-start.

The quick-start command restarts fuel-gauge calculations in the same manner as initial power-up of the IC. If the system power-up sequence is so noisy that the initial estimate of SOC has unacceptable error, the system microcontroller may be able to reduce the error by using quick-start. A quick-start is initiated by a rising edge on the QSTRT pin, or by writing 1 to the quick-start bit in the MODE register.

**Power-On Reset (POR)**

POR includes a quick-start, so only use it when the battery is fully relaxed. See the [Quick-Start](#) section. This command restores all registers to their default values. After this command, reload the custom model. See the [CMD Register \(0xFE\)](#) section.

**Hibernate Mode**

The ICs have a low-power hibernate mode that can accurately fuel gauge the battery when the charge/discharge rate is low. By default, the device automatically enters and exits hibernate mode according to the charge/discharge rate, which minimizes quiescent current (below 5 $\mu$ A) without compromising fuel-gauge accuracy. The ICs can be forced into hibernate or active modes. Force the IC into hibernate mode to reduce power consumption in applications with less than C/4-rate maximum loading. For applications with higher loading, Maxim recommends the default configuration of automatic control of hibernate mode.

In hibernate mode, the device reduces its ADC conversion period and SOC update to once per 45s. See the [HIBRT Register \(0x0A\)](#) section for details on how the IC automatically enters and exits hibernate mode.

**Alert Interrupt**

The ICs can interrupt a system microcontroller with five configurable alerts. All alerts can be disabled or enabled with software. When the interrupt occurs, the system microcontroller can determine the cause from the STATUS register.

When an alert is triggered, the IC drives the  $\overline{\text{ALRT}}$  pin logic-low and sets CONFIG.ALRT = 1. The  $\overline{\text{ALRT}}$  pin remains logic-low until the system software writes CONFIG.ALRT = 0 to clear the alert. The alert function is enabled by default, so any alert can occur immediately upon power-up. Entering sleep mode clears no alerts.

**Sleep Mode**

In sleep mode, the IC halts all operations, reducing current consumption to below 1 $\mu$ A. After exiting sleep mode, the IC continues normal operation. In sleep mode, the IC does not detect self-discharge. If the battery changes state while the IC sleeps, the IC cannot detect it, causing SOC error. Wake up the IC before charging or discharging. To enter sleep mode, write MODE.EnSleep = 1 and either:

Hold SDA and SCL logic-low for a period for  $t_{\text{SLEEP}}$ . A rising edge on SDA or SCL wakes up the IC.

Write CONFIG.SLEEP = 1. To wake up the IC, write CONFIG.SLEEP = 0. Other communication does not wake up the IC. POR does wake up the IC.

Therefore, applications that can tolerate 4 $\mu$ A should use hibernate mode rather than Sleep mode.

**I<sup>2</sup>C Interface**

The MAX20303 uses the two-wire I<sup>2</sup>C interface to communicate with a host microcontroller. The configuration settings and status information provided through this interface are detailed in the register descriptions. To simplify the use of existing code and drivers designed for interfacing with the ModelGauge fuel gauge, the MAX20303 appears as two devices on an I<sup>2</sup>C bus. The main device controlling the regulators, charger, and other system functions has the seven-bit slave address 0b0101000 (0x50 for writes, 0x51 for reads). Accessing the fuel gauge is done using the seven-bit slave address 0b0110110 (0x6C for writes, 0x6D for reads).

**Applications Information****I<sup>2</sup>C Interface**

The MAX20303 contains an I<sup>2</sup>C-compatible interface for data communication with a host controller (SCL and SDA). The interface supports a clock frequency of up to 400kHz. SCL and SDA require pullup resistors that are connected to a positive supply.

**Start, Stop, And Repeated Start Conditions**

When writing to the MAX20303 using I<sup>2</sup>C, the master sends a START condition (S) followed by the MAX20303 I<sup>2</sup>C address. After the address, the master sends the register address of the register that is to be programmed. The master then ends communication by issuing a STOP condition (P) to relinquish control of the bus, or a REPEATED START condition (Sr) to communicate to another I<sup>2</sup>C slave. See [Figure 8](#).

Figure 8. I<sup>2</sup>C START, STOP and REPEATED START Conditions

**Slave Address**

Set the Read/Write bit high to configure the MAX20303 to read mode. Set the Read/Write bit low to configure the MAX20303 to write mode. The address is the first byte of information sent to the MAX20303 after the START condition.

**Bit Transfer**

One data bit is transferred on the rising edge of each SCL clock cycle. The data on SDA must remain stable during the high period of the SCL clock pulse. Changes in SDA while SCL is high and stable are considered control signals (see the [Start, Stop, And Repeated Start Conditions](#) section). Both SDA and SCL remain high when the bus is not active.

**Single-Byte Write**

In this operation, the master sends an address and two data bytes to the slave device ([Figure 9](#)). The following procedure describes the single byte write operation:

The master sends a START condition

The master sends the 7-bit slave address plus a write bit (low)

The addressed slave asserts an ACK on the data line

The master sends the 8-bit register address

The slave asserts an ACK on the data line only if the address is valid (NAK if not)

The master sends 8 data bits

The slave asserts an ACK on the data line

The master generates a STOP condition

**Burst Write**

In this operation, the master sends an address and multiple data bytes to the slave device ([Figure 10](#)). The slave device automatically increments the register address after each data byte is sent, unless the register being accessed is 0x00, in which case the register address remains the same. The following procedure describes the burst write operation:

The master sends a START condition

The master sends the 7-bit slave address plus a write bit (low)

The addressed slave asserts an ACK on the data line

The master sends the 8-bit register address

The slave asserts an ACK on the data line only if the address is valid (NAK if not)

The master sends 8 data bits

The slave asserts an ACK on the data line

Repeat 6 and 7 N-1 times

The master generates a STOP condition

Figure 9. Write Byte Sequence

Single Byte Read

In this operation, the master sends an address plus two data bytes and receives one data byte from the slave device (Figure 11). The following procedure describes the single byte read operation:

- The master sends a START condition
- The master sends the 7-bit slave address plus a write bit (low)
- The addressed slave asserts an ACK on the data line
- The master sends the 8-bit register address

- The slave asserts an ACK on the data line only if the address is valid (NAK if not)
- The master sends a REPEATED START condition
- The master sends the 7-bit slave address plus a read bit (high)
- The addressed slave asserts an ACK on the data line
- The slave sends 8 data bits
- The master asserts a NACK on the data line
- The master generates a STOP condition

Figure 10. Burst Write Sequence

Figure 11. Read Byte Sequence

**Burst Read**

In this operation, the master sends an address plus two data bytes and receives multiple data bytes from the slave device (Figure 12). The following procedure describes the burst byte read operation:

The master sends a START condition

The master sends the 7-bit slave address plus a write bit (low)

The addressed slave asserts an ACK on the data line

The master sends the 8-bit register address

The slave asserts an ACK on the data line only if the address is valid (NAK if not)

The master sends a REPEATED START condition

The master sends the 7-bit slave address plus a read bit (high)

The slave asserts an ACK on the data line

The slave sends 8 data bits

The master asserts an ACK on the data line

Repeat 9 and 10 N-2 times

The slave sends the last 8 data bits

The master asserts a NACK on the data line

The master generates a STOP condition

**Acknowledge Bits**

Data transfers are acknowledged with an acknowledge bit (ACK) or a not-acknowledge bit (NACK). Both the master and the MAX20303 generate ACK bits. To generate an ACK, pull SDA low before the rising edge of the ninth clock pulse and hold it low during the high period of the ninth clock pulse (see Figure 13). To generate a NACK, leave SDA high before the rising edge of the ninth clock pulse and leave it high for the duration of the ninth clock pulse. Monitoring for NACK bits allows for detection of unsuccessful data transfers.

Figure 12. Burst Read Sequence

Figure 13. Acknowledge

## Application Processor Interface

Several of the MAX20303's functions are controlled by an Application Processor (AP). AP commands read and write configuration settings to the internal registers. Data transfer is handled by the AP controller and is triggered by writes to APCmdOut. There is a 5ms (typ), 9ms (max) latency associated with setting commands. This delay increases if the command requires additional processes such as ADC measurements, haptic autotune, etc. When the transfer is complete,  $\overline{\text{INT}}$  goes low, APCmdResponseInt (bit seven of direct register Int2 (0x05)) is set, and the controller writes the value of the received opcode to APResponse. Reading the data in APResponse provides verification of the successful execution of an opcode.

### AP Write

To set configuration registers, data must first be written to the APDataOut0-5 registers. Tables 47 to 190 detail the functions of each APDataOut\_ register for a given opcode. Once APDataOut0-5 contain the configuration bytes, writing an opcode to APCmdOut signals the controller to transfer data to the internal registers. Note that a write opcode only transfers the number of bytes defined by the command. The controller ignores the contents of all extra APDataOut\_ registers. See [Figure 14](#) for the structure of an AP write procedure with an APResponse opcode check.

Figure 14. Executing a Write Opcode and Reading the MAX20303 Response

### AP Read

To read a configuration register, APCmdOut is set to a read opcode. Read opcodes signal the controller to transfer the internal register contents to the APDataIn0-5 registers. When the transfer is complete, APDataIn0-5 contain the stored configuration settings or operation results and can be read over I2C. Because read opcodes expect no inputs, any data stored in APDataOut0-5 is ignored. [Figure 15](#) illustrates the AP read processes.

### AP Launch

Certain commands trigger additional functions in the MAX20303. These commands, such as ADC\_Measure\_Launch (opcode 0x53) and HPT\_Autotune (opcode 0xAC), may require additional elaboration time for taking measurements and computing the result. When the process is complete, results may be read from APDataIn0-5 as in normal AP Read commands.

### Write-Protected Commands and Fields

If the factory configured bit WriteProtect is enabled, the AP commands InputCurrent\_Config\_Write (0x10), Charger\_Config\_Write (0x14), and Charger\_ControlWrite (0x1A) are not accessible. If the application processor issues a request to one of these commands, the device will respond with the SysError code MA\_SYSEERROR\_APCMD\_WRITEPROTECT.

A settings are also write protected, but it is possible to write these settings using an additional field in the command that contains a password.

**Input Current Limit Commands**

*Note: Registers written using opcodes 0x10, 0x14, 0x16, 0x18, 0x1A, and 0x1C are reset on charger insertion. After receiving a UsbOk interrupt, wait 10ms before writing any data using these opcodes. Failure to wait 10ms may result in the data being overwritten to the default.*

|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FtrCntrEn    | Zero-Crossing Event Capturing Filter Enable<br>Can also be set using opcode 0xBA<br>0 = Zero-crossing measured using single comparator.<br>1 = Zero-crossing measured using an up/down counter (samples at 25.6MHz). Samples the output of the comparator for the whole duration of the enabled window (wide or narrow). The counter starts at zero (mid-code) and will end at a positive or negative code depending on whether the average zero-crossing event occurs before or after than the expected time. The closer the zero-crossing is on average to the expected time, the closer to zero code returned at the end of the window will be. Phase error (in 25.6MHz period units) can be calculated by dividing the resulting code at the end of the window by 2. The usage of the up/down counter enables filtering/noise rejection that could otherwise cause a systematic shift in the phase error detected. |
| IniDly[4:0]  | Number of sine wave periods to be skipped before (re)starting BEMF measurement after:<br>Start of vibration pattern.<br>Change of output polarity (e.g., braking)<br>Programmed percentage output amplitude (w.r.t. V <sub>FS</sub> ) becomes again higher than EmfSkipTh[6:0] after having previously gone below it. Can also be set using Opcode 0xAF.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| WidWdw [5:0] | Wide window duration for BEMF zero-crossing detection (LSB is (1/64) of currently imposed sinewave period).<br>Can also be set using Opcode 0xB0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| NarWdw [5:0] | Narrow window duration for BEMF zero-crossing detection (LSB is (1/64) of currently imposed sinewave period).<br>Can also be set using Opcode 0xB0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## Fuel Gauge I<sup>2</sup>C Registers

### Register Summary

All registers must be written and read as 16-bit words; 8-bit writes cause no effect. Any bits marked X (don't care) or read only must be written with the rest of the register, but the value written is ignored by the IC. The values read from don't care bits are undefined. Calculate the register's value by multiplying the 16-bit word by the register's LSb value, as shown in [Table 191](#).

#### VCELL Register (0x02)

The MAX20303 measures VCELL between the V<sub>DD</sub> and GND pins. VCELL is the average of four ADC conversions. The value updates every 250ms in active mode and every 45s in hibernate mode.

#### SOC Register (0x04)

The ICs calculate SOC using the ModelGauge algorithm. This register automatically adapts to variation in battery size since ModelGauge naturally recognizes relative SOC.

The upper byte least-significant bit has units of 1%. The lower byte provides additional resolution.

The first update is available approximately 1s after POR of the IC. Subsequent updates occur at variable intervals depending on application conditions.

#### MODE Register (0x06)

The MODE register allows the system processor to send special commands to the IC (see [Figure 16](#)).

- **Quick-Start** generates a first estimate of OCV and SOC based on the immediate cell voltage. Use with caution; see the [Quick-Start](#) section.
- **EnSleep** enables sleep mode. See the [Sleep Mode](#) section.
- **HibStat** indicates when the IC is in hibernate mode (read only).

#### VERSION Register (0x08)

The value of this read-only register indicates the production version of the IC.

**Table 191. Register Summary**

| ADDRESS      | REGISTER NAME | 16-BIT LSb    | DESCRIPTION                                                                                                    | READ/WRITE | DEFAULT |
|--------------|---------------|---------------|----------------------------------------------------------------------------------------------------------------|------------|---------|
| 0x02         | VCELL         | 78.125μV/cell | ADC measurement of VCELL.                                                                                      | R          | —       |
| 0x04         | SOC           | 1%/256        | Battery state of charge.                                                                                       | R          | —       |
| 0x06         | MODE          | —             | Initiates quick-start, reports hibernate mode, and enables sleep mode.                                         | W          | 0x0000  |
| 0x08         | VERSION       | —             | IC production version.                                                                                         | R          | 0x001_  |
| 0x0A         | HIBRT         | —             | Controls thresholds for entering and exiting hibernate mode.                                                   | R/W        | 0x8030  |
| 0x0C         | CONFIG        | —             | Compensation to optimize performance, sleep mode, alert indicators, and configuration.                         | R/W        | 0x971C  |
| 0x14         | VALRT         | —             | Configures the VCELL range outside of which alerts are generated.                                              | R/W        | 0x00FF  |
| 0x16         | CRATE         | 0.208%/hr     | Approximate charge or discharge rate of the battery.                                                           | R          | —       |
| 0x18         | VRESET/ID     | —             | Configures VCELL threshold below which the IC resets itself, ID is a one-time factory-programmable identifier. | R/W        | 0x96__  |
| 0x1A         | STATUS        | —             | Indicates overvoltage, undervoltage, SOC change, SOC low, and reset alerts.                                    | R/W        | 0x01__  |
| 0x40 to 0x7F | TABLE         | —             | Configures battery parameters.                                                                                 | W          | —       |
| 0xFE         | CMD           | —             | Sends POR command.                                                                                             | R/W        | 0xFFFF  |

**HIBRT Register (0x0A)**

To disable hibernate mode, set HIBRT = 0x0000. To always use hibernate mode, set HIBRT = 0xFFFF (see [Figure 17](#)).

- **ActThr** (active threshold): If at any ADC sample  $|OCV-CELL|$  is greater than ActThr, the IC exits hibernate mode. 1 LSb = 1.25mV.
- **HibThr** (hibernate threshold). If the absolute value of CRATE is less than HibThr for longer than 6min, the IC enters hibernate mode. 1 LSb = 0.208%/hr.

**CONFIG Register (0x0C)**

See [Figure 18](#)

- **RCOMP** is an 8-bit value that can be adjusted to optimize IC performance for different lithium chemistries or different operating temperatures. Contact Maxim for instructions for optimization. The POR value of RCOMP is 0x97.
- **SLEEP** forces the IC in or out of sleep mode if Mode.EnSleep is set. Writing 1 forces the IC to enter sleep mode, and 0 forces the IC to exit. The POR value of SLEEP is 0.
- **ALSC** (SOC change alert) enables alerting when SOC changes by at least 1%. Each alert remains until STATUS.SC is cleared, after which the alert automatically clears until SOC again changes by 1%. Do not use this alert to accumulate changes in SOC.
- **ALRT** (alert status bit) is set by the IC when an alert occurs. When this bit is set, the  $\overline{ALRT}$  pin asserts low. Clear this bit to service and deassert the  $\overline{ALRT}$  pin. The power-up default value for ALRT is 0. The STATUS register specifies why the  $\overline{ALRT}$  pin was asserted.
- **ATHD** (empty alert threshold) sets the SOC threshold, where an interrupt is generated on the  $\overline{ALRT}$  pin and can be programmed from 1% up to 32%. The value is (32 - ATHD)% (e.g., 00000b → 32%, 00001b → 31%, 00010b → 30%, 11111b → 1%). The POR value of ATHD is 0x1C, or 4%. The alert only occurs on a falling edge past this threshold.

Figure 16. MODE Register Format

Figure 17. HIBRT Register Format

Figure 18. CONFIG Register Format

VALRT Register (0x14)

This register is divided into two thresholds: Voltage alert maximum (VALRT.MAX) and minimum (VALRT.MIN). Both registers have 1 LSb = 20mV. The IC alerts while VCELL > VALRT.MAX or VCELL < VALRT.MIN (see Figure 19).

CRATE Register (0x16)

The IC calculates an approximate value for the average SOC rate of change. 1 LSb = 0.208% per hour (not for conversion to ampere).

VRESET/ID Register (0x18)

See Figure 20.

- ID is an 8-bit read-only value that is one-time programmable at the factory, which can be used as an

identifier to distinguish multiple cell types in production. Writes to these bits are ignored.

- VRESET[7:1] adjusts a fast analog comparator and a slower digital ADC threshold to detect battery removal and reinsertion. For captive batteries, set to 2.5V. For removable batteries, set to at least 300mV below the application's empty voltage, according to the desired reset threshold for your application. If the comparator is enabled, the IC resets 1ms after VCELL rises above the threshold. Otherwise, the IC resets 250ms after the VCELL register rises above the threshold.
- Dis. Set Dis = 1 to disable the analog comparator in hibernate mode to save approximately 0.5μA

Figure 19. VALRT Register Format

Figure 20. VRESET/ID Register Format

STATUS Register (0x1A)

An alert can indicate many different conditions. The STATUS register identifies which alert condition was met. Clear the corresponding bit after servicing the alert (see [Figure 21](#)).

Reset Indicator:

- **RI** (reset indicator) is set when the device powers up. Any time this bit is set, the IC is not configured, so the model should be loaded and the bit should be cleared.

Alert Descriptors:

These bits are set only when they cause an alert (e.g., if CONFIG.ALSC = 0, then SC is never set).

- **VH** (voltage high) is set when VCELL has been above ALRT.VALRTMAX.
- **VL** (voltage low) is set when VCELL has been below ALRT.VALRTMIN.
- **VR** (voltage reset) is set after the device has been reset regardless of EnVr.
- **HD** (SOC low) is set when SOC crosses the value in CONFIG.ATHD.
- **SC** (1% SOC change) is set when SOC changes by at least 1% if CONFIG.ALSC is set.

Enable or Disable VRESET Alert:

- **EnVr** (enable voltage reset alert) when set to 1 asserts the  $\overline{\text{ALRT}}$  pin when a voltage-reset event occurs under the conditions described by the VRESET/ ID register.

TABLE Registers (0x40 to 0x7F)

Contact Maxim for details on how to configure these registers. The default value is appropriate for some Li+ batteries.

To unlock the TABLE registers, write 0x57 to address 0x3F, and 0x4A to address 0x3E. While TABLE is unlocked, no ModelGauge registers are updated, so reload as soon as possible by writing 0x00 to address 0x3F, and 0x00 to address 0x3E.

CMD Register (0xFE)

Writing a value of 0x5400 to this register causes the device to completely reset as if power had been removed (see the *Power-On Reset (POR)* section). The reset occurs when the last bit has been clocked in. The IC does not respond with an I<sup>2</sup>C ACK after this command sequence.

Figure 21. STATUS Register Format

Table 192. Register Bit Default Values

| REGISTER<br>BITS | DEFAULT VALUE       |                     |                    |                    |                     |                     |                    |                       |                       |                       |                       |

## Revision History

| REVISION NUMBER | REVISION DATE | DESCRIPTION                                                                                                                                                                                                                                                                                                        | PAGES CHANGED                                                                 |
|-----------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------|
| 0               | 12/16         | Initial release                                                                                                                                                                                                                                                                                                    | —                                                                             |
| 1               | 1/17          | Removed future product status from MAX20303A and made various other changes to register maps                                                                                                                                                                                                                       | 19, 24, 45–49, 51, 60–62, 68–71, 73, 75, 77, 82, 103–105, 125–127, 131, 146   |
| 2               | 3/17          | Updated Figure 1e and removed future product status from MAX20303D                                                                                                                                                                                                                                                 | 49, 146                                                                       |
| 3               | 4/17          | Removed future product status from MAX20303C part numbers and increased V <sub>LIIN</sub> minimum value in <i>Electrical Characteristics</i> table                                                                                                                                                                 | 27, 146                                                                       |
| 4               | 5/17          | Corrected external CP cap, updated figures, and added Table 193 and Table 194                                                                                                                                                                                                                                      | 1, 12, 31, 34, 38, 41, 43, 47, 49, 50, 51, 56, 70, 93, 121, 123, 145, 146–149 |
| 5               | 10/17         | Updated Benefits and Features section, Timer Suspend Threshold typ in the <i>Electrical Characteristics</i> table, Driver Amplitude section, Table 63, Table 131, and Table 135. Corrected typos in Table 44 and Table 127. Added a new Table 193, and renumbered Tables 194–195. Replaced Table 192.              | 1, 19, 57, 86, 94, 124–125, 126, 128, 144–151                                 |
| 6               | 10/17         | Updated Direct Access I <sup>2</sup> C Register Map table, and removed future part designation from MAX20303GEWN+ and MAX20303GEWN+T in the <i>Ordering Information</i> table.                                                                                                                                     | 68–69, 151                                                                    |
| 7               | 2/18          | Updated the <i>Power Switch and Reset Control</i> section and Table 1. Removed future part designation from MAX20303HEWN+ and MAX20303HEWN+T in the <i>Ordering Information</i> table.                                                                                                                             | 44, 51, 151                                                                   |
| 8               | 9/19          | Updated Table 1, <i>Direct Access I<sup>2</sup>C Register Map</i> , Table 12, Table 55, Table 92, Table 192, Table 193, Table 194, Table 195, and added MAX20303JEWN+, MAX20303JEWN+T, MAX20303KEWN+, MAX20303KEWN+T, MAX20303LEWN+ and MAX20303LEWN+T as future products to the <i>Ordering Information</i> table | 51, 68, 73, 90, 108, 144, 146–151                                             |
| 9               | 10/19         | Updated Table 193, and removed future product designations from MAX20303JEWN+, MAX20303JEWN+T, MAX20303LEWN+, and MAX20303LEWN+T in the <i>Ordering Information</i> table                                                                                                                                          | 146, 151                                                                      |
| 10              | 1/20          | Updated the title and <i>Direct Access I<sup>2</sup>C Register Map</i> section; updated Tables 6, 10, 13–14, 192–195; added MAX20303MEWN+ and MAX20303MEWN+T to the <i>Ordering Information</i> section and removed future product designations from MAX20303KEWN+ and MAX20303KEWN+T                              | 1–152                                                                         |

For pricing, delivery, and ordering information, please visit Maxim Integrated's online storefront at <https://www.maximintegrated.com/en/storefront/storefront.html>.

Maxim Integrated cannot assume responsibility for use of any circuitry other than circuitry entirely embodied in a Maxim Integrated product. No circuit patent licenses are implied. Maxim Integrated reserves the right to change the circuitry and specifications without notice at any time. The parametric values (min and max limits) shown in the *Electrical Characteristics* table are guaranteed. Other parametric values quoted in this data sheet are provided for guidance.

Компания «Life Electronics» занимается поставками электронных компонентов импортного и отечественного производства от производителей и со складов крупных дистрибьюторов Европы, Америки и Азии.

С конца 2013 года компания активно расширяет линейку поставок компонентов по направлению коаксиальный кабель, кварцевые генераторы и конденсаторы (керамические, пленочные, электролитические), за счёт заключения дистрибьюторских договоров

Мы предлагаем:

- Конкурентоспособные цены и скидки постоянным клиентам.
- Специальные условия для постоянных клиентов.
- Подбор аналогов.
- Поставку компонентов в любых объемах, удовлетворяющих вашим потребностям.
- Приемлемые сроки поставки, возможна ускоренная поставка.
- Доставку товара в любую точку России и стран СНГ.
- Комплексную поставку.
- Работу по проектам и поставку образцов.
- Формирование склада под заказчика.
- Сертификаты соответствия на поставляемую продукцию (по желанию клиента).
- Тестирование поставляемой продукции.
- Поставку компонентов, требующих военную и космическую приемку.
- Входной контроль качества.
- Наличие сертификата ISO.

В составе нашей компании организован Конструкторский отдел, призванный помогать разработчикам, и инженерам.

Конструкторский отдел помогает осуществить:

- Регистрацию проекта у производителя компонентов.
- Техническую поддержку проекта.
- Защиту от снятия компонента с производства.
- Оценку стоимости проекта по компонентам.
- Изготовление тестовой платы монтаж и пусконаладочные работы.
